Globalization, Redistribution, and the Composition of Public Education Expenditures

Abstract

We analyze whether globalization affects the composition of public expenditures for education by integrating arguments from the Heckscher-Ohlin and the tax competition literature into a common theoretical framework. The model suggests that with increasing global integration, developing countries have strong incentives to shift public education expenditures towards lower education. In industrialized countries, on the other hand, globalization has an ambiguous effect on the composition of public education expenditures. We test and confirm these hypotheses with data on 86 countries over the 1999-2006 period.

JEL-Code: F15, H42, H52.

Keywords: globalization, public education, composition of public spending.

1 Introduction

Globalization is proceeding at a rapid pace. It is therefore not surprising that several social sciences continue to explore its various implications. Public economists are particularly interested in how global economic integration affects public policies; consequently, a large literature on this question has emerged over the years within the field of Public Economics.

Several authors argue that deepening economic integration may lead to the dissolution of the welfare state and cause social and political instability (Rodrik, 1997; Rudra, 2002). On the one hand, economic integration might increase international tax competition and thus cause lower tax rates on mobile firms (Lee and McKenzie, 1989; Devereux et al., 2008). As a consequence, the tax burden could shift from mobile (capital) to immobile (labor) production factors, and fewer resources might be available for redistributive programs. On the other hand, globalization is often associated with an increase in the cross-border mobility of individuals, which is expected to additionally strain the welfare state. First, because the wealthy and highly qualified can more easily defy high personal tax rates through emigration; second, because generous redistributive transfers might attract the poor and less qualified (Sinn, 2003).

The empirical implication of these arguments is that tax revenues and the amount of redistributive transfers will decline with deepening globalization. But even though these theoretical arguments are persuasive, the available empirical evidence is ambiguous. Shelton (2007) finds that trade openness has had no effect on total government expenditures for a panel of 100 countries over the 1970-2000 period.¹ Slemrod (2004) shows that there is a negative correlation between corporate tax rates and openness, even though total tax receipts seem to have been unrelated to openness. Rodrik (1998) and Ram (2009) find that more open countries have higher government expenditures.²

This empirical ambiguity is to some extent expected given that globalization may have conflictive effects on fiscal policy. Therefore, the individual effects of globalization could cancel each other out at the level of total government expenditures. In response to this problem, several authors have used less aggregated data, and explored whether globalization has had an effect on the composition of the public budget. Dreher et al. (2008) study in a notable contribution this question with a panel of 108 countries over the 1970-2001 period. However, they find that the composition of public expenditures has not been affected by globalization.

¹Note that the terms globalization and trade openness are used interchangeably in this literature. Globalization is, however, a broader concept than trade openness, and additionally implies, *inter alia*, a global convergence of cultures and political systems. For a more detailed discussion of the proper meaning of globalization see Bhagwati (2004) and Dreher et al. (2008).

²Alesina and Wacziarg (1998), however, present evidence that the positive correlation between openness and government size is driven by the fact that smaller countries have a larger public sector and are also more open than larger countries. Benarroch and Pandey (2008) oppose the causal conclusions in Rodrik (1998) by arguing that his models suffer from a reversed causality problem.

Even though Dreher et al. (2008) conduct a thorough analysis, it is possible that their level of aggregation is still too high. They consider relative shifts in, for example, total education and social security expenditures. The drawback of considering such broad spending categories is that the subtler effects of globalization on public budgets might be missed. That is, globalization might have affected the composition of expenditures *within* broad budget categories, while not changing their relative importance. With respect to public spending on education, for example, globalization could have affected the distribution of education expenditures between lower and higher education, while not affecting the relative importance of education expenditures as a whole vis-a-vis other expenditure categories.

Therefore, we explore in this study whether globalization has an effect on the composition of public education expenditures. More specifically, we analyze how globalization affects the allocation of public education expenditures on primary, secondary, and tertiary programs.

A noteworthy precursor to our study is Ansell (2008). He constructs a model that is based on the insight that industrialized and developing countries have different factor endowments. He derives that globalization will affect the returns to factors of production differently in industrialized and developing countries (see the next section for a more detailed discussion). His model leads to the conclusion that governments in developing countries will attach more importance to primary and less to tertiary education with deepening globalization, while those in industrialized countries will pursue the opposite policy. Even though he also presents some empirical evidence in support of this hypothesis, this particular research question is only one of several in his paper and not fully explored.³

We extend Ansell's work in various directions. First, while taking into account that globalization might affect factor prices in industrialized and developing countries differently, we additionally acknowledge the contributions of the literature on international tax competition (surveyed above) in our theoretical model. We argue in the model that globalization increases tax competition and thereby reduces the government's ability to redistribute income through the tax-transfer system. This, in turn, causes governments to rely increasingly on educational policies for redistributive purposes.⁴ Second, we also extend Ansell's empirical analysis by using a more sophisticated measure for the extent of globalization, applying panel data techniques, and controlling for potential endogeneity.

The remainder of this paper is structured as follows. In the next section, we develop a simple theoretical model to analyze the relationship between globalization and the composition of education expenditures. We test the implications of the model with panel data covering 86 countries over the 1999-2006 period in section 3. In section 4, we conclude.

³Other notable theoretical contributions on the impact of globalization on educational policies are Anderson (2005), Anderson and Konrad (2003), Haupt and Janeba (2009), and Viaene and Zilcha (2002). Apart from Ansell (2008), there is, to our knowledge, no further empirical study on the effect of globalization on the *composition* of education expenditures.

⁴As discussed in Hanushek et al. (2003), the idea of using educational policies as an alternative means of redistribution is fairly standard.

2 The model

2.1 Framework

Consider a country that is populated by two groups: individuals who are endowed with a low level of ability a_L (group L), and individuals who are endowed with a high level of ability $a_H > a_L$ (group H). These different levels of ability may originate from differences in inborn intelligence, or in the skills and opportunities that an individual “inherits” by being raised within a particular social class.

With respect to the masses of the two population groups, we assume that $M[L] > M[H]$. There are thus more low- than high-ability individuals, which is probably a realistic assumption for most countries. We also normalize $M[H] = 1$.

Each individual $i \in I$, $I = \{L, H\}$ produces an output y_I by combining her endowed ability a_I with a government-provided productivity-enhancing public good g_I . We assume that the production function of individual i is of the Cobb-Douglas type; it is given by $y_i = a_I^\beta g_I^{1-\beta}$, $\forall i \in I = \{L, H\}$ with $0 < \beta < 1$.

In our context, it is appropriate to think of g_I as different types of education expenditures. That is, g_L could be thought of as spending for lower education. A high value for g_L would then signal the government’s willingness to increase the income of the low-ability individuals by improving their educational opportunities. Conversely, g_H can be thought of as higher education expenditures, which increase the productivity of the high-ability individuals, but are of no direct use to the low-ability individuals.

Even though expenditures for lower education might in reality also directly benefit the high-ability individuals, any such benefits are likely to be smaller than those they would obtain through higher education expenditures. The assumption that the high-ability individuals do not benefit at all from lower education and the low-ability individuals not at all from higher education is a simple way to capture the fact that different societal groups prefer different compositions of the public budget. Incorporating cross benefits into the model would not qualitatively affect the argument we want to make, but would add several variables to the algebra.

It is apparent that industrialized countries have, inter alia, a relative abundance in high-skilled labor, whereas developing countries are relatively abundant in low-skilled labor. This implies that in a world of closed economies, wages for low-skilled labor should be *relatively* high in industrialized and *relatively* low in developing countries, while wages for high-skilled labor should be relatively low in industrialized and relatively high in developing countries.

One important effect of globalization is that firms in industrialized countries gain access to the low-skilled labor pool in developing countries, for example by relocating their production plants. This increases the demand for low-skilled workers in developing countries, while decreasing it in industrialized countries. Therefore, the returns to low-skilled labor are likely

to increase in developing and decrease in industrialized countries with deepening globalization. Conversely, the returns to high-skilled labor will decrease in developing and increase in industrialized countries with globalization.

Consequently, we need to account for this argument, which resembles the factor price equalization theorem from the Heckscher-Ohlin model, in our model. We do this by modeling the price at which the output of individual i can be sold as a function of globalization, which we denote with A . The price for the output of an individual i of type $I = \{L, H\}$ is thus given as $p_I = p_I[A]$. We assume that $p_H > p_L$ holds both in industrialized and developing countries. What differs in our model between industrialized and developing countries is the sign of dp_I/dA , the (marginal) effect of globalization on the output prices. It follows from our previous discussion that $dp_H/dA > 0$ and $dp_L/dA < 0$ holds for industrialized countries. In developing countries, the signs should be reversed, i. e., $dp_H/dA < 0$ and $dp_L/dA > 0$. While this is admittedly a highly simplified application of the insights from the Heckscher-Ohlin model,⁵ it captures the important result that international trade leads to a equalization of factor prices (Krugman and Obstfeld, 2005).

The market income of the individual i is then given by

$$\pi_i = p_I[A]y_i = p_I[A]a_I^\beta g_I^{1-\beta}, \forall i \in I = \{L, H\}. \quad (1)$$

Even though taxes can in principle only be collected after production has taken place, it is reasonable to assume that education expenditures are financed through taxation because any productivity enhancing government expenditures have to be paid eventually through tax revenue.⁶

The government's budget constraint is given by

$$T = M(L) g_L + g_H + R. \quad (2)$$

This equation states that a share $T - R$ of total tax revenues T is intended for education expenditures. The remaining portion $R > 0$ of the tax revenues is used for redistribution through cash transfers.

Since the low-ability individuals constitute the majority of the population, we assume that the government is exclusively interested in the welfare of this population group. This is a reasonable approximation of reality for democratic countries, and it might also be appropriate for certain types of autocratic states such as populist regimes.

We equate the welfare of an individual with her net-consumption level. The government has, in principle, two decision variables through which it can influence an individual's net-

⁵In the standard exposition of the Heckscher-Ohlin model, for example, international trade leads only *indirectly* to an equalization of factor prices by causing a convergence of prices for traded goods. In our model, however, we do not distinguish between factor and output prices for the sake of brevity. See Krugman and Obstfeld (2005) and Leamer (1995) for a more detailed discussion of the Heckscher-Ohlin model.

⁶See Alesina and Rodrik (1994) for a similar approach.

consumption level. It can, first, use education expenditures g_I , and, second, use direct transfers to redistribute income. We assume that the low-ability individuals are exempt from taxation. The high-ability individuals have to pay a proportional tax t on their market income. Total tax revenues are thus given by

$$T = t\bar{\pi}_H. \quad (3)$$

where $\bar{\pi}_H$ denotes the total income of the high-ability individuals as a group (i. e., the tax base), and is given by

$$\bar{\pi}_H = \int_{i \in H} p_H[A] a_i^\beta g_i^{1-\beta} di = p_H[A] a_H^\beta g_H^{1-\beta}. \quad (4)$$

Note that the total income of the high-ability individuals is equal to their average income because we have normalized the mass of this group to unity.

Given the above assumptions, the governments's objective function, i. e. the net-consumption of a representative individual belonging to the group of the low-ability individuals, is

$$\max_{g_L, g_H, t} V = \pi_L + \frac{1}{M[L]} R. \quad (5)$$

The net-consumption of a low-ability individual is thus given by her own market income π_L , and a per-capita transfer that is equal to the part of the tax revenues, R , used for the transfer payments divided by the population mass of the low ability individuals.

2.2 Mobility and the optimal tax rate

It follows immediately from the objective function that the government should always choose the highest possible tax rate. However, in reality, the government cannot freely choose the tax rate because it has to take into account that high tax rates reduce the tax base. Emigration of the richly-endowed is one of the most important explanations for an upper limit on redistribution through the tax-transfer system. Therefore, the equilibrium tax rate depends on the extent of international mobility, which we presume in the following to be related to the level of globalization.

We assume that these mobility decisions are made after production has taken place. This implies that a high ability individual, if she chooses to emigrate, takes the income she has already earned to the foreign country, but does not generate any additional income there.

To model these mobility decisions formally, let us presume that a high-ability individual will be indifferent between remaining in the country and emigrating if the following condition holds:

$$(1 - t) \pi_H = (1 - t^F - x[A]) \pi_H, \quad (6)$$

with t^F denoting the tax rate if the individual would emigrate (the “foreign” tax rate), and $x[A]$ denoting the costs that have to be incurred in the case of emigration. These costs can be thought of as the monetary representation of the “psychological” stress of losing contact with one’s acquaintances, or as the costs of relocating physical assets. They are incurred as a fraction of income because more wealthy individuals usually own more assets and will thus have higher relocation costs.⁷

The costs are modeled as a function of the extent of globalization A with $dx/dA < 0$. This assumption captures the fact that one effect of globalization is the lowering of transportation cost, which implies that it becomes easier to visit one’s acquaintances in the home country, or to relocate physical assets. Another aspect relates to the spread of English as a modern Lingua Franca and the emergence of a global culture, both of which might reduce the psychological costs of moving to a foreign country.

Solving equation 6 for the equilibrium domestic tax rate gives $t = t^F + x[A]$. It is straightforward to show that $dt/dA = dx/dA < 0$. That is, the equilibrium tax rate is a (decreasing) function of the extent of globalization, i. e. $t \equiv t^*[A]$ (it is also a function of the foreign tax rate, but we suppress this parameter in the following). This is a reasonable result given that globalization is often associated with intensifying tax competition and a decline in the tax burden of the wealthy.

2.3 The composition of public education expenditures

Taking into account equations 2 and 3, and that the eventual tax rate is a function of the level of globalization, the objective function of the government can be rewritten as follows

$$\max_{g_L, g_H} V_{t=t^*[A]} = \pi_L + \frac{1}{M[L]} (t^*[A] \bar{\pi}_H - (M[L]g_L + g_H)), \quad (7)$$

with the constraint $t^*[A] \bar{\pi}_H \geq M[L] g_L + g_H$.

Differentiating the objective function with respect to the g_i and assuming an interior solution⁸, we can show that the g_i will be chosen such that

$$\frac{g_H}{g_L} = (t^*[A] \chi[A])^{1/\beta} \frac{a_H}{a_L}, \quad (8)$$

with $\chi[A] = p_H[A]/p_L[A]$.

This equation implies that in equilibrium, the relative amount of resources allocated to higher education will increase with the equilibrium tax rate, the relative value of the output prices, and the relative value of the endowment of the high-ability individuals.

⁷We realize that this argument for treating the emigration costs as proportional to income does not equally well apply to the costs due to ‘psychological’ stress, but the proportionality assumption might still be appropriate because high-ability individuals usually have a more “valuable” network of acquaintances in the home country.

⁸This requires, in particular, that the tax rate in equilibrium $t^*[A]$ is sufficiently large

When international mobility is prohibitively costly and therefore the extent of globalization low, the tax rate can be set at $t^* = 1$. The government would then choose an allocation of g_H and g_L such that the relative share of g_H is given by $g_H/g_L = \chi[A]^{1/\beta}(a_H/a_L)$. Thus, the market income of the high-ability individuals will be relatively large. After redistribution, however, the income distribution would be reversed. In fact, the high-ability individuals will be completely expropriated.

This conclusion is of course unrealistic if it is taken literally. It does, however, mirror a particular pattern of fiscal policy that can be observed in several OECD and many developing countries. In the typical European welfare state, for example, higher education is provided either free of charge or is highly subsidized by the government, even though the majority of the electorate does not directly benefit from these expenditures. At the same time, average and marginal personal income tax rates are relatively high. At first sight, this pattern of fiscal policy makes little sense. According to our model, however, this policy might maximize the consumption possibilities of the income strata that have a low level of ability if tax competition is very low.

As argued by Poutvaara and Kanninen (2000), such a social consensus to finance higher education publicly may break down once the highly skilled can emigrate more easily. This can also be shown formally in our model by differentiating the first order condition in equation 8 with respect to the level of globalization:

$$\frac{d}{dA} \left(\frac{g_H}{g_L} \right) = \Lambda \times \left(\frac{dt^*[A]}{dA} \chi[A] + t^* \frac{d\chi[A]}{dA} \right), \quad (9)$$

with $\Lambda = (1/\beta) (t^*[A]\chi[A])^{(1-\beta)/\beta} (a_H/a_L)$.

Since Λ is unambiguously positive, the sign of expression 9 depends upon $(dt^*[A]/dA)\chi[A] + t^*(d\chi[A]/dA)$. First, note that we have shown in section 2.2 that $dt^*/dA < 0$ because globalization intensifies tax competition. The sign of $d\chi[A]/dA$, however, is less obvious. In fact, as argued above, it differs between industrialized and developing countries.

In developing countries, globalization decreases the returns to high-skilled and increases that to low-skilled labor. This implies that $d\chi/dA < 0$. Therefore, since both $dt^*/dA < 0$ and $d\chi/dA < 0$, expression 9 will be unambiguously negative in developing countries. In other words, developing countries will shift their educational policies in favor of lower education with deepening globalization.

In industrialized countries, on the other hand, globalization increases the returns to high skilled and reduces that to low-skilled labor. This implies that $d\chi/dA > 0$. Therefore, the sign of expression 9 is indeterminate because $dt^*/dA < 0$. In other words, governments in industrialized countries face conflictive incentives with respect to their educational policies. Whether globalization will induce them to shift their educational programs toward lower or higher education, or not at all, is therefore an empirical question. Given that industrialized

countries face conflictive incentives, however, one reasonable hypothesis is that globalization will be “neutral” for the composition of education expenditures in this group of countries.

3 Empirical results

3.1 Empirical model and data

In this section, we test the implications of our theoretical model by estimating several variants of the following general empirical model

$$y = \alpha_i + \omega_t + \beta \mathbf{x} + \delta \text{Globalization} + \gamma \text{Globalization} \times \text{Dev} + \epsilon, \quad (10)$$

where y is a measure for public expenditures for either primary, secondary, or tertiary education, α_i country fixed effects, ω_t year fixed effects, \mathbf{x} a vector of control variables (see below), and ϵ the error term.

In order to test the implications of our theory, we include a measure for globalization and its interaction with a dummy variable that is 1 for “developing” countries⁹. We are interested in the estimate for δ and γ , the coefficients attached to the globalization variable and its interaction with the developing country dummy: δ is the effect of globalization in industrialized countries, whereas $\delta + \gamma$ is its effect in developing countries. Note that we do not have to explicitly include the developing country dummy into this model because of the country fixed effects.

The theoretical model leads two related but distinct empirical predictions. First, the fact that the effect of globalization on the composition of education expenditures is ambiguous in industrialized but unambiguous in developing countries implies that with deepening globalization, developing countries will increase their spending for primary education and reduce their spending for tertiary education *at least as much* than industrialized countries. This implies that the estimate for γ should be weakly positive (i. e., $\gamma \geq 0$) for primary and weakly negative (i. e., $\gamma \leq 0$) for tertiary education. We label this prediction the *Relative Education Hypothesis (REH)* because it refers to the relative effect of globalization in developing countries as compared to industrialized countries.

The theoretical model also leads to a second prediction which we label the *Absolute Education Hypothesis (AEH)*. The fact that equation 9 in the theoretical section is unambiguously negative for developing countries suggests that these countries will increase their spending for

⁹ Any classification of countries as industrialized or developing is of course arbitrary. We take a conservative approach and classify the wealthy “Western” countries cum Japan and South Korea as industrialized. This implies that even OECD countries such as Turkey or Poland are classified as “developing”. Therefore, the term developing as used in this paper should not be understood as being synonymous with, for example, the Least Developed Countries (LDC). It should rather be understood as encompassing all countries except the most wealthy. See table 7 in the appendix for a complete list of how we have classified the countries in our sample.

primary and reduce that for tertiary education with deepening globalization. The testable implication of this theoretical result is that the marginal effect of globalization in developing countries, $\delta + \gamma$, should be significantly positive for primary and significantly negative for tertiary education.

Even though the model does not offer a clear prediction for secondary education expenditures, we also consider the impact of globalization on this type of educational program. With regard to this type of education expenditures, we presume that the effect of globalization will be less pronounced than for primary and tertiary education in both industrialized and developing countries.

Our preferred measure for public education expenditures for the three types of educational programs, i.e. the dependent variables in equation 10, are the expenditures per student, normalized through division by GDP per capita.

We prefer these measures to using “budget shares” (i.e., primary, secondary, and tertiary education expenditures as share of total education expenditures) because we must scale government spending on the three different educational programs by the number of students in these programs. This is done automatically when we use expenditures per student as dependent variable. We conduct, however, further below a sensitivity analysis by using the share of primary, secondary, and tertiary education expenditures in total education expenditures as dependent variable. A concise description of the dependent variables and their sources can be found in table 1.

With respect to the control variables in equation 10, our measure of globalization is the KOF-index developed by Dreher (2006). The KOF-index is based on three sub-indexes which capture the extent of economic, social, and political globalization. These three sub-indexes are aggregated into one single measure of globalization. We prefer this measure to the simple trade openness variable (exports plus imports divided by GDP) because it takes into account that globalization is a multi-dimensional phenomenon that has broader implications than only to increase international trade. In view of the research questions in this study, an appropriate measure of globalization should, inter alia, additionally capture to what extent English is used as a second language since the ability to communicate in the current Lingua Franca will directly impact international mobility.

We use a diverse set of additional control variables, which are listed in table 1. Most importantly, we include total education expenditures per student as percent of GDP per capita. This variable has to be controlled for since our aim is to investigate how the *relative* importance of primary, secondary, tertiary education expenditures (i.e., the composition of education expenditures) has changed with globalization.

We additionally include (i) the size of the population in order to capture economies of scale in the provision of public goods; (ii) total government expenditures as share of GDP in order to control for the economic importance of the public sector; (iii) GDP per capita in order to

capture how a country’s income level is related to the structure of education expenditures; and (iv) a measure of the government’s ideology in order to control for systematic partisan biases in education expenditures. The ideology variable is an index that is 1 when the government is left-wing with respect to economic policy, and else 0.¹⁰

One important variable for which do not explicitly control is the amount private education expenditures. Unfortunately, private education expenditures are difficult to measure for the poorer countries in our sample. However, the propensity of a country to finance education privately can be understood as a relatively time-constant country-specific characteristic. For example, private education expenditures have traditionally been and continue to be more important in Anglo-Saxon than in Continental European countries. We therefore use the country fixed effects to control for the importance of private education expenditures.

Apart from these control variables, we use several additional variables either as controls in the robustness checks, or as instruments, or both. These are, first, the gross enrollment rates for primary, secondary, or tertiary educational programs and, second, the population shares of the age groups relevant for each of the three types of educational programs. In addition, we also consider the amount of development aid paid to certain countries. We explain the rationale for using these variables in the respective sections; they are concisely described in table 1.

Our unbalanced dataset covers 86 countries, both developing and developed, over the 1999-2006 period. Summary statistics for all variables used in the subsequent regressions are collected in table 5; a list of the countries that are considered in this study can be found in table 7. Both tables are in the appendix.

Inter alia, the summary statistics in table 5 reveal that the average expenditures per student as percent of GDP per capita are much higher for tertiary (64.48 %) than for either primary (16.29%) or secondary programs (22.73%). The same holds with respect to the variability in the three expenditure types as revealed by the standard deviations.

3.2 Baseline models

We collect the baseline results in table 2. We estimate a set of four models for each of the different types of education expenditures. All models include the full set of economic and political control variables, and country and year fixed effects (results for these are not reported). For hypothesis tests, we always use robust standard errors. At the bottom of the table (in the row labeled *Glob. at Dev=1*), we report the marginal effect of globalization in developing countries (i. e., the estimate of $\delta + \gamma$) for those models in which we include the interaction between globalization and the developing countries dummy.

¹⁰Note that this ideology variable is derived from the DPI dataset. Whereas this dataset distinguishes between right, center, left, and *other* governments, we use, for compactness, a 0-1 classification. We code left-wing governments as 1 and all other governments as 0.

Table 1: DEFINITION AND SOURCE OF VARIABLES

Label	Description	Source
Dependent variables		
Primary/Student	Primary education expenditures per student divided by GDP per capita	UNESCO Institute for Statistics
Secondary/Student	Secondary education expenditures per student divided by GDP per capita	UNESCO Institute for Statistics
Tertiary/Student	Tertiary education expenditures per student divided by GDP per capita	UNESCO Institute for Statistics
Control variables and instruments		
Total/Student	Total education expenditures per student divided by GDP per capita	UNESCO Institute for Statistics
Globalization	KOF index of globalization	Dreher (2006)
Population	Population size	Penn World Table 6.3
Gov. share	Government expenditures as share of GDP	Penn World Table 6.3
GDP p. c.	(real) GDP per capita	Penn World Table 6.3
Ideology	Index of government ideology with respect to economic policy, left-wing=1, else 0	Own calculation based on DPI 2006 Dataset (Beck et al., 2001)
Aid	Development aid /GDP	World Development Indicators
Primary enrollment	Gross enrollment rate in primary education	World Development Indicators
Secondary enrollment	Gross enrollment rate in secondary education	World Development Indicators
Tertiary enrollment	Gross enrollment rate in tertiary education	World Development Indicators
Primary pop.	School age population - Primary, as share of total population	UNESCO Institute for Statistics
Secondary pop.	School age population - Secondary, as share of total population	UNESCO Institute for Statistics
Tertiary pop.	School age population - Tertiary, as share of total population	UNESCO Institute for Statistics
Additional dependent variables for sensitivity analysis		
Primary/ Total edu. exp.	Primary education expenditures as share of total education expenditures (logit transformation)	UNESCO Institute for Statistics
Secondary/Total edu. exp.	Secondary education expenditures as share of total education expenditures (logit transformation)	UNESCO Institute for Statistics
Tertiary/Total edu. exp.	Tertiary education expenditures as share of total education expenditures (logit transformation)	UNESCO Institute for Statistics

These four models successively impose fewer assumptions on the data, thereby making the estimates more robust while simultaneously decreasing their efficiency. If all models produce qualitatively similar results, however, we should be reasonably confident that our conclusions are valid.

The first model for each spending category (entitled FE 1) includes the globalization variable but not its interaction with the developing countries dummy. By not including the interaction effect in this model, we effectively assume that globalization has the same effect in both industrialized and developing countries.

The second model (entitled FE 2) includes the interaction effect and thus takes into account that the marginal effect of globalization might differ between industrialized and developing countries.

The third model (entitled IV), while controlling for all variables that are considered in the second model, takes additionally into account that total education expenditures and the expenditures for primary, secondary, and tertiary education are by construction simultaneously determined. We deal with this endogeneity problem by instrumenting total education expenditures. The IV estimator, while being less efficient than OLS, leads to consistent estimates. We consider this as our preferred model because it is probably the most reasonable compromise between consistency and efficiency.

In the fourth model (entitled IV & CL), re-estimate of the third model, but conduct the hypothesis tests on the basis of clustered standard errors. This model is therefore robust to arbitrary forms of autocorrelation, but may be particularly inefficient.

We use as instruments for total education expenditures in the third and fourth model (i) the gross enrollment rates and (ii) the population shares of the relevant age groups for the three educational programs (school age population). To minimize the potential for endogeneity problems, we use in each set of regressions for one type of educational program the enrollment and population shares in the other two types. For example, we use as instruments in the models with secondary education expenditures as dependent variable the gross enrollment rate in primary and tertiary education, and the population shares of the age groups relevant for primary and tertiary education. The only exception is the model with primary education expenditures. Here, the Hansen J test for overidentification rejects the null when the gross enrollment rate in tertiary education is used as an instrument. We therefore exclude this variable from our set of instruments in the models with primary education expenditures as dependent variable.

The theoretical rationale for using the different enrollment rates and population shares as instruments is that they are likely to be correlated with total education expenditures.¹¹ As

¹¹Note that the direction of the correlation is not trivial. While a higher *overall* gross enrollment rate should be positively correlated with higher total education expenditures, this is not necessarily true for the individual gross enrollment rates in the three educational programs. That is, a higher *gross* enrollment rate in a lower-level educational program implies that the gross enrollment rate in the next higher program tends to be smaller, for example because of repeaters. Since education expenditures per student are on average larger

indicated by the overidentification tests in table 2, the instruments perform well with respect to this test in all models. The relevance tests, however, indicate that the set of instruments may be weak in the model for secondary education expenditures when clustered standard errors are used.

According to the results in table 2, the estimate for δ is significantly positive in the model for primary, insignificant in the model for secondary, and significantly negative in the model for tertiary education expenditures when the interaction term is not included (the FE 1 models). These results seem to suggest that globalization is positively associated with primary, unrelated with secondary, and negatively related with tertiary education expenditures.

The remaining models in table 2, however, reveal that these results are driven by the effects of globalization in developing countries. The interaction effect is, as predicted by the *REH* hypothesis, always positive for primary and always negative for tertiary education expenditures. In fact, the interaction effect is even significantly different from 0 (this, however, is not necessary to confirm the theory which only predicts that the interaction effects will be *weakly* positive or negative, respectively). The signs of the interaction effects thus confirm Hypothesis *REH*.

The second hypothesis, *AEH*, is also confirmed by our results. As the row entitled *Glob. at Dev=1* shows, the marginal effects of globalization in developing countries, $\delta + \gamma$, is significantly positive in the model for primary and significantly negative in the model for tertiary education expenditures. The effect of globalization in industrialized countries, δ (when the developing country dummy is 0), on the other hand, is always insignificant. In other words, globalization has apparently led to a relative increase in funding for primary and a reduction in funding for tertiary education in developing countries, while displaying a “neutral” effect in the industrialized world.

Note also the the marginal effect of globalization in the model for secondary education expenditures has always, both for industrialized and developing countries, a value that is in between the estimates for the marginal effects in the models for primary and tertiary education expenditures.

With respect to the other control variables, we find that an increase in education expenditures increases spending for all three educational programs since the coefficient for this variable is consistently positive. Apart from total education expenditures, only the population and GDP per capita variable are sometimes significant. When countries become more prosperous, they seem to spend more on primary and secondary education. When countries become more populous, on the other hand, they seem to spend less on primary education.

at higher levels of education, a higher gross enrollment rate at some lower level is therefore not necessarily negatively correlated with total education expenditures.

3.3 Sensitivity analysis

In this section, we investigate the robustness of our results. In the first set of robustness checks, we divide our sample in industrialized and developing countries and estimate the baseline model separately for each of the two groups of countries. In doing so, we allow not only the coefficient on the globalization variable, but also all other coefficients to vary between industrialized and developing countries.

The results are collected in table 3. For each type of educational program, we estimate two individual models. First, we estimate a pooled OLS model to exploit both the between and within variation (since pooled OLS models take the between variation into account, they can be considered as an additional robustness check). Thereafter, we include country fixed effects and re-estimate the model while only using the within-variation. All models also include year fixed effects, and hypothesis tests are conducted with robust standard errors. Total education expenditures are instrumented with the same instruments as in the baseline models.

First, note that the signs of the coefficient are always the same in the pooled OLS and the fixed effects models. The significance levels, however, tend to be lower in the fixed effects models, but the t-statistics are in general relatively high. Note also that the overidentification test sometimes performs poorly in the pooled OLS models while it always performs well in the fixed effects models. This indicates that the pooled OLS models probably suffer from an omitted variables bias.

Overall, the results from these robustness checks confirm the baseline results. In developing countries, globalization apparently leads to higher primary education expenditures while it seems to have a negative effect on tertiary education expenditures. Conversely, globalization seems to have no effect on education expenditures in industrialized countries as indicated by the insignificant coefficients in the fixed effects models. In other words, the baseline results are confirmed by this set of robustness checks.

In table 4, we report the results from a second set of robustness checks. In these regressions, we study whether the results in the baseline regressions are sensitive to (i) outliers, (ii) to using “budget shares” (primary, secondary, and tertiary education expenditures as share of total education expenditures) instead of spending per student as dependent variable, and (iii) to controlling for development aid. The specification is similar to the baseline models in the sense that we include the interaction of the globalization with that of the developing country dummy variable and all other control variables from the baseline model.

⁴ The p-values for the overidentification and relevance tests are reported at the bottom of the table

In the models entitled *Outliers*, we re-estimate our preferred model (IV in table 2) after dropping all observations for which a Grubbs test suggest that they are an outlier.¹² We use a significance level of 95% in the models for secondary and tertiary education expenditures. This reduces the number of observations in the model for tertiary education expenditures by a large amount, and in the model for secondary education expenditures somewhat moderately. In the model with primary education expenditures, however, no observations are regared as outliers at a significance level of 95%. We therefore reduce the significance level sucessively for primary education expenditures. But even at a significance level of 50 %, only two observations are considered as outliers for this type of expenditures, which suggests that most countries spend similar per capita amounts (scaled by their respective GDP per capita) for primary education.

In the models entitled *Budget*, we use the alternative measure for public spending on the three types of educational programs. The dependent variables in these models are the budget shares. Since the budget shares are constrained to be between 0 and 100, using them as dependent variables violates the assumptions for OLS to be appropriate. We therefore transform the dependent variables by applying the logistic function before conducting the estimations.

Since the number of students in the three educational programs do not appear at the left-hand side in the *Budget* models, we have to adapt the right hand-side of equation 10 by explicitly including both the population shares of the relevant age groups and the gross enrollment rates. This is necessary because the “demand” for a particular type of educational spending will increase with the number of student and their enrollment rates.

In the models entitled *Aid*, we additionally include into the baseline model the amount of development aid divided by GDP as an additional control variable. The rational for including this variable is that donor countries may insist that developing countries use aid for certain types of educational programs. According to Bloom et al. (2006), for example, international donor agencies have generally emphasized lower and deemphasized higher education in developing countries.¹³

As in the baseline models, we need to instrument total education expenditures per student in the *Outliers* and *Aid* models. We do that by using the same instruments as in the baseline models. In the *Budget* models, we do not use instruments and thus report the simple fixed effects estimates. All models include year fixed effects and use robust standard errors for hypothesis tests.

The results for this set of robustness checks are collected in table 4. They largely confirm the baseline results. The interaction effect is generally positive in the primary and negative

¹²The Grubbs test has been implemented by Couderc (2007) in Stata.

¹³Note that our original data for the aid variable had missing observations for “wealthy” countries. We replaced these missing observations with 0 to ensure that we can include these countries in the regressions. Note furthermore that several developing countries in our sample had a *negative* value for the development aid variable in some years. We replaced these values with 0, too.

in the tertiary education expenditures model. The only exception is the *Budget* model for primary education expenditures, where the interaction effect is close to 0 (but still positive). On the other hand, the *Budget* model performs well for tertiary education expenditures. Overall, we consider this as a confirmation of the *REH* hypothesis.

The *AEH* is also largely confirmed. The coefficients in the row entitled with *Glob. at Dev=1* are always positive for primary education expenditures and always negative for tertiary education expenditures. For tertiary education expenditures, however, the coefficient is insignificant in the *Budget* model, but still negative. Note also that the overidentification test is rejected in the *Outlier* model. This is probably due to the large reduction in the sample size.

Overall, both sets of robustness checks largely confirm the baseline results and thus reaffirm the validity of the *REH* and *AEH* hypotheses.

4 Conclusion

In this paper, we have analyzed whether globalization is related to the composition of public education expenditures. We first developed a theoretical model which suggested that globalization causes governments in developing countries to adjust public education expenditures away from higher and towards lower education. For industrialized countries, on the other hand, the model suggested an ambiguous effect.

Based on these theoretical results, we formulated two empirical hypotheses. The *Relative Education Hypothesis* stated that developing countries will increase their spending for primary education and reduce their spending for tertiary education at least as much as industrialized countries. The *Absolute Education Hypothesis*, on the other hand, stated that developing countries will increase their spending for primary and reduce that for tertiary education with deepening globalization. In the empirical part of our paper, we found robust evidence, i. e., in the baseline models and in sensitivity analyses, for both hypotheses.

Our results thus show that globalization affects the structure of public education expenditures. It apparently shifts the composition of education expenditures towards lower education in developing countries, which might, in the long run, benefit the poor by increasing their productivity. We therefore conclude that governments in developing countries react to globalization by taking steps that mitigate, to some extent, its potentially harmful distributional consequences.

In industrialized countries, on the other hand, globalization seems to have been largely neutral for the composition of public education expenditures. Since the distributional consequences of globalization for low-skilled individuals in industrialized countries are apparently not alleviated by shifts in the composition of public education expenditures, additional measures might be necessary (Sinn, 2005).

An issue that deserves further attention is whether the pattern between globalization and public education expenditures that we have observed in the empirical investigations is indeed due to the “transmission channels” considered in our theoretical model. While the model provides one explanation for the empirical pattern, there might be competing arguments. A more complete test of our theory should, for example, explicitly show that globalization (i) has reduced the tax burden of the high-skilled while (ii) increasing, with an appropriate time lag, the market income of the low-skilled in developing countries due to the shift in education expenditures.

This, however, is difficult with the available data. With respect to the first point, the problem is to find an appropriate measure of the tax burden of firms and individuals. While this is already a contentious issue for industrialized countries, the situation is even more difficult for developing countries for which the underlying data on taxes is sketchy. With respect to the second point, the unavailability of disaggregated data on the market income of the high- and low-skilled is, especially in developing countries, the main problem. Finding an appropriate strategy to differentiate between different theoretical arguments for the observed empirical pattern is therefore a promising avenue for future research.

Acknowledgments

We are grateful to the participants of the 3rd CESifo Workshop on Political Economy in Dresden, in particular Heike Auerswald, Henning Bohn, Christian Lessmann, and Thierry A. Verdier, for helpful comments and suggestions.

Table 6: CROSS-CORRELATION TABLE

Variables	Primary/ Student	Secondary/ Student	Tertiary/ Student	Primary/ Total edu. exp.	Secondary/ Total edu. exp.	Tertiary/ Total edu. exp.
Primary/Student	1.000					
Secondary/Student	0.422	1.000				
Tertiary/Student	0.009	0.509	1.000			
Primary/Total	-0.054	-0.004	0.314	1.000		
Secondary/Total edu. exp.	0.071	0.201	-0.316	-0.671	1.000	
Tertiary/Total edu. exp.	0.102	0.052	0.132	-0.387	-0.109	1.000

Table 7: INCLUDED COUNTRIES

Argentina (D)	Hungary (D)	Oman (D)
Australia	Iceland	Panama (D)
Austria	India (D)	Paraguay (D)
Azerbaijan (D)	Iran (D)	Peru (D)
Barbados (D)	Ireland	Philippines (D)
Belgium	Israel (D)	Poland (D)
Belize (D)	Italy	Portugal
Benin (D)	Jamaica (D)	Romania (D)
Bolivia (D)	Japan	Rwanda (D)
Brazil (D)	Kenya (D)	Samoa (D)
Bulgaria (D)	Korea	Senegal (D)
Burkina Faso (D)	Kuwait (D)	Slovak Republic (D)
Burundi (D)	Latvia (D)	Slovenia (D)
Cameroon (D)	Lesotho (D)	South Africa (D)
Cape Verde (D)	Lithuania (D)	Spain
Chad (D)	Madagascar (D)	Swaziland (D)
Chile (D)	Malaysia (D)	Sweden
Colombia (D)	Mali (D)	Tajikistan (D)
Costa Rica (D)	Malta (D)	Thailand (D)
Cote d'Ivoire (D)	Mauritania (D)	Trinidad & Tobago (D)
Cyprus (D)	Mauritius (D)	Tunisia (D)
Czech Republic (D)	Mexico (D)	Turkey (D)
Denmark	Mongolia (D)	Ukraine (D)
El Salvador (D)	Morocco (D)	United Arab Emirates (D)
Estonia (D)	Namibia (D)	United Kingdom
Finland	Nepal (D)	United States
France	Netherlands	Uruguay (D)
Greece	New Zealand	Vanuatu (D)
Guyana (D)	Norway	

¹ Countries classified by us as “developing” are indicated with a “D” in parentheses

² See footnote 9 for an explanation of the criteria according to which a country is classified as developing or industrialized
