# Collusion, Blackmail and Whistle-Blowing

## Abstract

Whistle-blowing is usually regarded as a way to identify abuse and wrongdoing on the part of governments and corporations. In this paper we show how, at a micro level, whistle-blowing can be used as a designer tool to prevent opportunistic behavior, that takes the form of collusion or blackmail, on the part of members of a simple hierarchical structure. We focus on a three layered principal-supervisor-agent structure and show how the principal can use whistle-blowing as a way to prevent the supervisor and the agent from colluding to the detriment of the principal. To understand our mechanism we need to explicitly define the penalty a party has to incur for walking away from a collusive agreement. Rewarding whistle-blowing, creates incentives for the uninformed colluding party to walk out of the side deal and report to the principal that collusion took place. This threat clearly reduces the informed party's incentive to participate in side deals. It also serves as a potential blackmail threat between the colluding parties. However, careful use of whistle-blowing allows the principal to eliminate opportunities for blackmail.

JEL-Code: D730, D780, D830.

Keywords: collusion, blackmail, whistle-blowing and communication.

April 2015

This paper partially replaces a previous version entitled “Avoiding Collusion through Discretion” (Felli and Hortala-Vallve, 2011). We greatly benefited from the comments and suggestions of Philippe Aghion, Richard Arnott, Giuseppe Bertola, Sandro Brusco, Francesca Cornelli, Donald Cox, Mathias Dewatripont, Peter Diamond, Antoine Faure-Grimaud, Franklin M. Fisher, Oliver Hart, Andrea Ichino, Jean-Jacques Laffont, David Martimort, John Moore, Patrick Rey, Lars Stole, Jean Tirole, Miguel Villas-Boas, Oved Yosha and of seminar participants at numerous institutions during the exceedingly long gestation of this research project.

## 1. Introduction

### 1.1. Overview

Whistle-blowing is an important phenomenon both in public life and in the corporate world. High profile whistle-blowers such as Edward Snowden for the NSA, Sherron Watkins for Enron and Irène Frachon for Servier (among many others) have left a lasting and sometimes controversial impression on public opinion about the power of whistle-blowing and its disciplinary role within public and corporate life. However, in all these cases whistle-blowing is understood as the disclosure (in the public interest) of an illegal or damaging practice to the press or other media platforms in the name of the public interest. This usually leads to the indictment of the organization that the whistle-blower is working for.<sup>1</sup>

The most commonly observed form of whistle-blowing is within crime prevention. For example, in Italy the use of the *pentiti* (informants) whom in exchange for protection and reduced sentences reported on the internal activity and structure of criminal organizations, allowing the judicial system (led by the Antimafia Pool of Palermo) to provide the first substantial blow to organized crime (Sicilian Mafia) in the form of the *maxiprocesso*, the criminal trial of the entire mafia organization at the end of the eighties.<sup>2</sup>

In this paper we explore a very different role for whistle-blowing. We explore how rewarding whistle-blowing can be used as a mechanism design tool to prevent detrimental or unwanted opportunistic behavior such as collusion or blackmail within an organization.

The key idea is very simple. Consider a stylized three-layered hierarchical structure: a principal, a supervisor and an agent. Suppose that the agent has private information on his productive ability and the supervisor only observes an imperfect signal of such ability. The principal can elicit the information from the supervisor but by doing so he introduces the possibility of collusion between the supervisor and the agent: an agent whose ability is higher than a certain value can extract larger rents when the principal believes he is a low type. However, to reach a collusive agreement the agent and the supervisor need to communicate and define the terms of the agreement. In so doing, the supervisor might become more informed about the productivity of the agent and the principal can reward the supervisor

---

<sup>1</sup>The literature on whistle-blowing is vast, see Miceli, Near, and Dworkin (2008) for a complete overview of the recent developments in multiple disciplines on the issue.

<sup>2</sup>See Lupo (2009) for a detailed account of the role of *pentiti* in the *maxiprocesso*.

leaking such information. If this is the case, the agent will refuse to participate in the collusive bargaining process to avoid losing the informational rent promised by the principal and collusion will be prevented. In the mechanism we present, the principal transfers the informational rent from the agent to the supervisor if the latter reports the information revealed during collusion or, equivalently, blows the whistle and reports that collusion took place and in so doing costlessly prevents harmful collusion.

Clearly the supervisor is able to exploit this additional information revealed during collusion only if she can breach the collusion agreement even if at a cost. In what follows we explicitly model the enforceability of collusion, in particular the cost an individual incurs by breaching a collusive agreement. The principal is then able to prevent collusion by introducing in the contract to the supervisor a clause that compensates the supervisor for the cost incurred when breaching the collusive agreement. Notice that because the final outcome will be that the agent refuses to participate in collusion this clause never applies in equilibrium and hence collusion is prevented at zero cost to the principal.

Allowing the supervisor to report that collusion took place comes at a cost. It creates the opportunity for the supervisor to blackmail the agent by threatening to blow the whistle even in the absence of any collusion unless the agent pays part of his informational rent to the supervisor. In what follows we show that whistle-blowing once again can solve the problem. Allowing the agent to report the supervisor's threat to the principal is enough to prevent blackmail in equilibrium. Moreover, if rewards for whistle-blowing are carefully chosen the agent's option to blow the whistle does not introduce further blackmail opportunities on the part of the agent.

The rest of the paper is organized in the following way. After a brief discussion of the related literature, Section 2 sets up the model. Section 3 analyzes the effects of collusion. In Section 4 we present a first optimal mechanism that allows the principal to prevent collusion in a costless way. Section 5 first shows that this optimal mechanism is liable for blackmail on the part of the supervisor and then modifies this mechanism so as to prevent all forms of collusion and blackmail. Section 6 concludes. For ease of exposition all proofs are presented in the Appendix.

### 1.2. Related Literature

Our analysis is closely related to two strands of the literature on organizations and contracts: one on delegation, pioneered by Arrow and Radner (1979), and the other on collusion, pioneered by Tirole (1986).

The existing literature on delegation focuses on its informational costs and benefits and on their interplay with incentives and technological complementarities or substitutabilities within the organization (Bolton and Dewatripont, 1994, Severinov, 2008) but has not considered the strategic role of an increase of discretionary power — a form of delegation — as a tool for preventing undesired collusive behavior between members of the organization (Bolton and Farrell, 1990, Hortala-Vallve and Sanchez-Villalba, 2010, Melumad, Mookherjee, and Reichelstein, 1995, Radner, 1993, Strausz, 1997).

On the other hand, the literature on collusion has depicted the problem as a costly one. It has modeled collusion as a fully enforceable side contract ignoring the possibility for the principal to induce one of the colluding parties to breach the side contract and report to the principal that collusion took place. In this way, the side contract is made disadvantageous for the remaining colluding parties (Faure-Grimaud, Laffont, and Martimort, 2003, Laffont and Martimort, 1997, Tirole, 1986).

While the early literature on collusion (starting from Tirole 1986) has analyzed collusion under hard or verifiable information,<sup>3</sup> more recently a number of papers have considered collusion-proof mechanisms in the presence of soft or unverifiable information (Laffont and Martimort 1997, 1999, 2000 and Faure-Grimaud, Laffont, and Martimort 1999, 2000, 2001, 2003). The last four papers are the closest to ours. They consider an incentive contract involving a principal, a supervisor and an agent and allow parties to setup fully enforceable collusive side contracts. They show that the *collusion-proof principle* (Laffont and Martimort, 1997) holds in this environment. The optimal mechanism is equivalent to a mechanism that in equilibrium does not allow the parties of the contract to engage in collusion. In other words, the optimal contract is the solution to the principal's payoff maximization problem, provided that supervisor and agent are not involved in collusion (as well as the standard individual rationality and incentive compatibility constraints). In addition, Faure-Grimaud, Laffont, and Martimort (2003) show that the *equivalence principle* holds, and that delegation,

---

<sup>3</sup>See for example Kofman and Lawarrée (1993, 1996).

when interpreted as an increase in the discretionary power of members of the organization, is a way to implement the optimal collusion-proof mechanism.

The approach we present here fits into their framework, and both the collusion-proof principle and the equivalence principle apply. In other words, the optimal mechanism we construct is such that the agent and the supervisor do not engage in collusion and an increase of the parties' discretionary power is a way to implement such a mechanism. However, we differ from these papers in that we explicitly model what it means for a side contract to be binding. We then allow the mechanism designer or principal to offer a mechanism that compensates the uninformed party for breaching the side deal and reporting the existence of the side deal to the principal.<sup>4</sup> In other words, we enlarge the message space of both the supervisor and the agent in the general mechanism that the principal offers them. When collusion takes place under asymmetric information, these enlarged message spaces serve the role of preventing any collusion and blackmail on the equilibrium path.

A number of papers have explicitly considered the effect of delegation on parties' incentives to engage in collusive agreements. Baliga and Sjöström (1998) have explored the effect of delegation in a moral hazard setting in the presence of colluding parties' limited liability. They identify the optimal delegation mechanism that achieves the outcome that is optimal in the absence of collusion.<sup>5</sup> This parallels our findings yet we do not rely on limited liability but rather on the colluding parties' option to breach the side contract at a cost.

Che and Kim (2006) and Celik (2009) both analyze delegation in the presence of collusion in a hidden information framework. Both papers ask whether delegation can achieve the same outcome that is optimal in the absence of collusion. While Che and Kim (2006) reach a positive answer in a very general framework, both in terms of the technology and the number of parties involved in collusion, possibly excluding some of the parties from the side deal, they do impose restrictions on the correlation between the colluding parties' information structure. Celik (2009), on the other hand, focuses on an organizational and informational structure similar to the one we consider here. He shows that delegation is not necessarily

---

<sup>4</sup>In this respect our approach is similar to the augmented revelation mechanisms (Ma, Moore, and Turnbull, 1988, Mookherjee and Reichelstein, 1990) that allow a mechanism designer (the principal) to prevent strategic coordination — as opposed to collusion — among agents. See also Demsky and Sappington (1989) for a hierarchical model where coordination between the supervisor and the agent is a concern that needs to be addressed by the optimal mechanism selected by the principal.

<sup>5</sup>See also Kessler (2000) for a related point.

an optimal mechanism. In contrast to these papers, the mechanism we suggest provides the colluding parties with the incentive to breach the side contract and exploit the information they learn during collusion to their advantage and to the disadvantage of the other parties. This is the reason why in our framework increasing discretion is optimal.<sup>6</sup>

The economic literature on whistle-blowing has mainly focused on its effects on antitrust policy and crime prevention.<sup>7</sup> This literature has identified the optimal leniency program that may destabilize cartels or criminal organizations by identifying the optimal amount of leniency that destroys the trust of the repeated (cartel) relationship (Motta and Polo, 2003, Spagnolo, 2004) or the optimal rewards to employees for blowing the whistle to authorities on the cartel's existence (Aubert, Rey, and Kovacic, 2006). We differ from this literature in focusing on whistle-blowing as a mechanism design tool of the principal and explicitly addressing the effects that rewarding whistle-blowing has on increasing the supervisor's opportunity to blackmail the agent.

Finally, we have to mention the literature that focuses on the interplay of collusion, blackmail and whistle-blowing. Khalil, Lawarrée, and Yun (2010) explore the close relationship between bribery and extortion. They show that in the presence of soft information, it is optimal to allow bribery to occur in equilibrium even if it is feasible to deter both. The reason for this is that in their paper the coalition incentive constraints are interlinked. The key difference with our analysis is the use of whistle-blowing as the tool that allows the principal to prevent both collusion and blackmail (bribery and extortion in their terminology) at no cost.<sup>8</sup> Leppamaki (1997, Ch. 3) also considers explicitly the interplay of whistle-blowing and blackmail in a contractual setting. The key difference is that while Leppamaki (1997, Ch. 3) analyzes blackmail in an incomplete-contract dynamic framework, in what follows we solve for the principal's static mechanism design problem.

---

<sup>6</sup>Quesada (2005) explicitly models the *informed principal* problem that may arise when collusion takes place under asymmetric information. This occurs when the party offering the side contract has private information not available to the other party. In our context collusion does not lead to an informed principal situation for two competing reasons. The supervisors and the agent's information structures are nested: the supervisor knows less than the agent. We follow Laffont and Martimort (1997) and model collusion in a way that is agnostic on the extensive form of the collusion game. In other words, our results do not rely on the identity of the "principal" in the side contract or how the collusive negotiation is structured.

<sup>7</sup>See Spagnolo (2008) for an extended survey of the effects of whistle-blowing on antitrust policy, and Gambetta and Reuter (1995) for its effects on prosecuting organized crime.

<sup>8</sup>See also Hindriks, Keen, and Muthoo (1999) and Polinsky and Shavell (2001) for an analysis of both corruption and extortion in a taxation and law enforcement setting, respectively.

## 2. The Model

### 2.1. The Parties

We model a simple three-level hierarchy. The top of the hierarchy is the residual claimant of profits: the principal ( $P$ ). The bottom layer is the only level that actually produces any output: the agent ( $A$ ). The intermediate level consists of a supervisor ( $S$ ), who is capable of collecting information about the agent's relevant characteristics.

*The agent* is the productive unit of the hierarchy. He is endowed with a productivity parameter  $\theta^A$ ,  $\theta^A \in \Theta^A \equiv \{\theta_1^A, \theta_2^A\}$ ,  $\theta_2^A > \theta_1^A$ . He may or may not exert a productive effort  $e^A \in \mathbb{R}$ , and both effort and productivity will generate an output  $x$  according to the following simple technology:

$$x = \theta^A + e^A \quad (1)$$

The agent is assumed to be risk neutral in income. His utility function is linear in income and strictly concave in effort. Disutility of effort is expressed, in monetary terms, by  $d(e^A)$ , where  $d'(\cdot) > 0$ ,  $d''(\cdot) > 0$ ,  $d'''(\cdot) > 0$ , for all  $e^A > 0$ ;  $d(0) = d'(0) = 0$ ,  $d(e^A) = 0$ , for all  $e^A < 0$ .<sup>9</sup> The agent's objective function is then:  $w - d(e^A)$ ; his reservation wage is  $\bar{w}$ .

*The supervisor* has a monitoring role. She does not contribute directly to the productive process, but just provides information. If requested, she can supply the information to the principal. This is modeled by assuming that the supervisor observes a noisy signal,  $\theta^S \in \Theta^S \equiv \{\theta_1^S, \theta_2^S\}$ ,  $\theta_2^S > \theta_1^S$ , of the agent's productivity parameter  $\theta^A$ . This signal is *soft* or *unverifiable* information, in the sense that an outside party — the principal in particular — has no way to verify the real value of the signal besides asking the supervisor for a report and inducing, through incentives, truthful revelation. This signal is observed by the supervisor at no cost.<sup>10</sup>

The supervisor is risk averse: her utility function  $V(s)$  is strictly concave in the salary  $s$ :  $V'(\cdot) > 0$ ,  $V''(\cdot) < 0$ . The supervisor has an outside option with a reservation salary  $\bar{s}$ .

*The principal* is risk neutral, and is the residual claimant of the organization.

---

<sup>9</sup>The role of negative effort is to keep things simple and allow the high productivity agent to mimic the low productivity agent. The assumption on the third derivative of the disutility function assures concavity of the optimization problems considered later.

<sup>10</sup>In principle, the supervisor might have to spend a costly effort to get a strictly informative signal, as in Demsky and Sappington (1989). However, such generalization does not add much to the analysis of collusion, while considerably complicating the notation and the presentation of the model.

### 2.2. The Information Structure

The principal is the least informed party in the organization. His information set includes only the final levels of output  $x$ . The supervisor costlessly observes the noisy signal  $\theta^S$  of the agent's productivity  $\theta^A$ , and observes  $x$ . Finally, the agent has the best information structure: he knows  $\theta^A$ , and can observe both the signal  $\theta^S$  and  $x$ .<sup>11</sup> We take  $x$  to be the only *verifiable* information of the model, while  $\theta^A$  is *observable* only to the agent and  $\theta^S$  is *observable* to both the agent and the supervisor.

The agent's productivity  $\theta^A$  and the supervisor's signal  $\theta^S$  are positively, but imperfectly, correlated. Let:

$$q_i = Pr\{\theta^S = \theta_1^S \mid \theta^A = \theta_i^A\} \quad i \in \{1, 2\} \quad (2)$$

That is,  $q_1$  is the probability that the signal  $\theta_1^S$  is correct and  $q_2$  is the probability that the same signal is not correct. We take  $\theta^S$  to be a strictly but not fully informative signal of  $\theta^A$ :

$$0 < q_2 < \frac{1}{2} < q_1 < 1 \quad (3)$$

### 2.3. The Timing and Solution Concept

Before contracting,  $\theta^A$  and  $\theta^S$  are determined by nature and are the agent's and the supervisor's private information. As mentioned above the supervisor only observes the realization of  $\theta^S$  while the agent observes the realizations of both  $\theta^S$  and  $\theta^A$ . The principal's beliefs about  $\theta^A$  and  $\theta^S$  are then characterized by the prior  $\pi = Pr\{\theta^A = \theta_1^A\}$  and the conditional distribution  $q_i$  as in (2) above, while the supervisor's beliefs, after observing the realization of  $\theta^S$ , are:

$$\begin{aligned} p_1 &= Pr\{\theta^A = \theta_1^A \mid \theta^S = \theta_1^S\} = \frac{q_1\pi}{q_1\pi + q_2(1-\pi)} \\ p_2 &= Pr\{\theta^A = \theta_1^A \mid \theta^S = \theta_2^S\} = \frac{(1-q_1)\pi}{(1-q_1)\pi + (1-q_2)(1-\pi)} \end{aligned} \quad (4)$$

Negotiations take place in which the principal is assumed to have all the bargaining power. He proposes a *take-it-or-leave-it* contractual offer  $C = (C^A, C^S)$  to both the agent and the supervisor, which specifies a schedule of compensations for them.

Supervisor and agent simultaneously and independently decide whether to accept or reject

---

<sup>11</sup>The fact that  $A$  observes  $\theta^S$  is clearly a simplifying assumption. It provides us a simple framework in which collusion may take place between the agent and the supervisor.

the principal's offer. If the agent rejects the offer, negotiation with both parties ends and the game ends. If the supervisor rejects the offer, negotiation proceeds involving only the agent. The game then becomes a standard two tier principal-agent problem.<sup>12</sup> If the principal wishes, he can make degenerate offers to the supervisor, which amount to a decision on his part to negotiate only with the agent. If both supervisor and agent accept the offer a contract is signed.

After the contract is signed, the collusive negotiation between the supervisor and the agent takes place. In Section 3 below we provide a general characterization of this negotiation.

At a predetermined time — between the initial contracting date and the date at which the agent produces output  $x$  — the supervisor produces a report  $r$  of her observed signal that becomes public information.<sup>13</sup> The agent then exerts his productive effort, the outcome of production becomes publicly observable and remunerations are paid according to the contract  $C$ .<sup>14</sup> We assume that all of this structure – summarized in the figure below – is common knowledge to all the parties.

Revelation Principle implies that, without loss of generality, we can restrict attention to the following revelation game. Everything proceeds in the way described above up to the collusion game. Then the supervisor announces the signal she has observed and the agent announces his productivity to the principal. The principal then dictates the agent's effort level and the remunerations to the supervisor and agent. Finally, the agent exerts the effort

<sup>12</sup>Alternatively, the principal could make a unique offer to the agent that specifies a contractual arrangement, if the supervisor accepts the principal's offer and a different arrangement if the supervisor rejects the principal's offer; nothing would change.

<sup>13</sup>In principle it might be of use for the principal to ask the agent, as well as the supervisor, to report the signal  $\theta^S$ . This is not the case in our framework independently of whether the parties may collude or not. Indeed, the optimal mechanism we derive in the presence and in the absence of collusion induces the supervisor to report the truth at no explicit cost for the principal.

<sup>14</sup>We take the timing of the supervisor's report as exogenously given. This is a simplifying assumption. However, our main result — the fact that collusion can be prevented at no additional costs — suggests a reason why the principal might want to specify the timing we analyze. See Felli (1990, Chapter 2, Section 6) for a discussion of the case in which the timing of the supervisor's report is endogenous.

chosen by the principal.

In the revelation game the supervisor's strategy space is the set of all possible mappings from the signal space  $\Theta^S$  into her message space  $\Theta^S$ . The agent, on his part, reports his own productivity parameter to the principal at the same time as the supervisor's report. The agent's strategy space is the set of all possible mappings from the space of the productivity parameters  $\Theta^A$  into the message space  $\Theta^A$ .

The mechanism specifies a salary for the supervisor, a wage for the agent and an output as functions of the agent's and supervisor's reports:

$$C = [s(\hat{\theta}^A, \hat{\theta}^S), w(\hat{\theta}^A, \hat{\theta}^S), x(\hat{\theta}^A, \hat{\theta}^S)]$$

If only the agent accepts the principal's contract offer then the mechanism boils down to a standard principal agent problem.<sup>15</sup>

In what follows we focus on the Perfect Bayesian Equilibria (PBE) of this game (Fudenberg and Tirole, 1991).

#### 2.4. *Honest Agent and Supervisor*

We derive first the benchmark case: the optimal contracts when both the agent and the supervisor are *honest* in the sense that neither of them engage in collusion and/or blackmail.

The simple structure of this environment allows the risk neutral principal to pay a constant salary to the risk averse supervisor

$$s(\hat{\theta}_i^S, \hat{\theta}_j^A) = \bar{s} \quad \forall i, j \in \{1, 2\} \quad (5)$$

and induce her to report the truth.<sup>16</sup>

The principal inherits, in this way, the information structure of the supervisor and can sign a contract with the agent that induces him to report the truth. This incentive contract

---

<sup>15</sup>In this case the optimal mechanism is  $[w(\hat{\theta}^A), x(\hat{\theta}^A)]$ .

<sup>16</sup>In case of indifference we assume that each party behaves in the way the principal wants it to behave according to the outstanding contracts. This tie-breaking rule is used to avoid multiple equilibria in the subgame played by the supervisor and the agent that arises when both parties are indifferent between their actions. The same result could be obtained by augmenting the *honest* mechanism described in this section, as in Ma, Moore, and Turnbull (1988), using nuisance strategies that allow the principal to induce the supervisor and the agent to coordinate on the equilibrium that the principal desires.

is contingent on the information  $\theta^S$  that the supervisor reports as well as the agent's report. The optimization problem that defines the agent's incentive contract is then

$$\begin{aligned}
& \max_{\{x_{ij}, w_{ij}\}} \pi [q_1 (x_{11} - w_{11}) + (1 - q_1) (x_{12} - w_{12})] \\
& \quad + (1 - \pi) [q_2 (x_{21} - w_{21}) + (1 - q_2) (x_{22} - w_{22})] \\
& \text{s.t. } w_{2j} - d(x_{2j} - \theta_2^A) \geq w_{1j} - d(x_{1j} - \theta_2^A) \quad \forall j \in \{1, 2\} \\
& \quad w_{1j} - d(x_{1j} - \theta_1^A) \geq \bar{w} \quad \forall j \in \{1, 2\}
\end{aligned} \tag{6}$$

where  $x_{ij} = x(\hat{\theta}_i^A, \hat{\theta}_j^S)$  and  $w_{ij} = w(\hat{\theta}_i^A, \hat{\theta}_j^S)$  for every  $i \in \{1, 2\}$  and every  $j \in \{1, 2\}$ . Problem (6) is standard. The principal's expected profit is maximized subject to the *incentive compatibility* constraints for the high productivity agent and the *individual rationality* constraints for the low productivity agent. We omit individual rationality constraint for the high type and incentive compatibility constraint for the low type since these constraints are not binding in equilibrium.

From Problem (6) we obtain:

$$x_{21} = x_{22} = x_2 > x_{11} > x_{12} \tag{7}$$

$$w_{21} - d(x_2 - \theta_2^A) > w_{22} - d(x_2 - \theta_2^A) > \bar{w} \tag{8}$$

$$w_{11} - d(x_{11} - \theta_1^A) = w_{12} - d(x_{12} - \theta_1^A) = \bar{w} \tag{9}$$

$$w_{21} - d(x_2 - \theta_2^A) = w_{11} - d(x_{11} - \theta_2^A) \tag{10}$$

$$w_{22} - d(x_2 - \theta_2^A) = w_{12} - d(x_{12} - \theta_2^A) \tag{11}$$

These conditions, together with (5), fully characterize what we here label the optimal *honest* contract.

The following Proposition 1 highlights the key feature of the *honest* contract relevant for our analysis of collusion.

**Proposition 1:** *The premium paid in equilibrium to the high productivity agent is higher if the supervisor reports  $\hat{\theta}_1^S$  rather than  $\hat{\theta}_2^S$ :  $w_{21} > w_{22}$ . ■*

The intuition behind this result is simple. The principal's costs of inducing a high productivity agent to separate himself from a low productivity agent are of two types: a premium, in

utility terms, for the high productivity agent and an inefficient effort (output) level that the low productivity agent is required to produce.<sup>17</sup> Whenever the supervisor tells the principal that she thinks the agent has low productivity — that is she has observed a low signal  $\theta_1^S$  — the principal updates his prior distribution increasing the probability that the agent has a low productivity  $\theta_1^A$ . This increases, in expected terms, the costs of having the low productivity agent produce an inefficient level of output, while reducing, in expected terms, the costs of a premium for the high productivity agent. Of course, the situation is symmetric and opposite whenever the supervisor reports to the principal a high signal  $\theta_2^S$ . Therefore, the principal, in equilibrium, trades-off these two costs and offers a higher premium to the high productivity agent, if the supervisor’s report is low, than if it is high — Proposition 1 and equation (8) — and requires the low productivity agent to exert a higher effort, if the supervisor’s report is low, than if it is high — equation (7).

A final question is whether in this world a principal would want to hire a supervisor in the first place. The answer depends on the reservation salary of the supervisor  $\bar{s}$ . If the constant salary paid to the supervisor does not exceed the principal’s gains generated by the availability of the signal  $\theta^S$  the principal strictly prefers to hire a supervisor.<sup>18</sup>

### 3. Collusion

#### 3.1. *The Collusive Contract*

In our setup collusion takes place between two asymmetrically informed parties: the agent and the supervisor. Therefore, in principle it is possible that during the collusion negotiation the uninformed party, the supervisor, learns the private information of the informed party, the agent. Of course, depending on the extensive form of the collusion negotiation this revelation of information might occur before the uninformed party commits to the collusive agreement or after this occurs. The implications of this timing differ depending on how “enforceable” the collusion agreement is: whether the uninformed party can walk away from collusion and what penalties for breach she is required to pay if she does. In modeling collusion we want

---

<sup>17</sup>Inefficiency is defined here with respect to an hypothetical first best, obtained in the case the principal observes perfectly the productivity or the effort of the agent.

<sup>18</sup>The proof that an additional strictly informative signal generates a positive welfare improvement to the principal goes as follows. The standard two tier principal-agent optimization problem can always be written in the form of Problem (6) adding the two constraints  $x_{ih} = x_{ik}, \forall h \neq k, h, k \in \{1, 2\}$ . These two constraints turn out to be binding at the optimum. Equation (7) shows that this is not true whenever the information reported by the supervisor is available. Thus, the principal is strictly better off in the latter case.

to specify a general model that encompasses this additional source of information for the supervisor and allows her to walk away from the collusive agreement, possibly at a cost.

The key assumption of our model is that negotiation of the collusive contract takes place between asymmetrically informed parties. This typically leads to multiple equilibria. What matters for our analysis is whether these equilibria separate the two types of agent during the collusion subgame. Indeed, all separating equilibria reveal the type of the agent to the supervisor hence the information of the supervisor improves.

In what follows we do not specify an extensive form for the collusion negotiation game.<sup>19</sup> Instead we follow Laffont and Martimort (1997) and assume the existence of a *collusion designer*. The colluding parties report their private information to the collusion designer. In our setup only the informed party, the agent, reports his private information, we denote this report  $\tilde{\theta}_j^A$ ,  $j \in \{1, 2\}$ . The designer then assigns to the colluding parties an allocation of surplus through the transfer that the agent makes to the supervisor  $\beta(\tilde{\theta}_j^A)$ ,  $j \in \{1, 2\}$ , a given report  $\hat{\theta}^S(\tilde{\theta}_j^A)$ ,  $j \in \{1, 2\}$ , that the supervisor makes to the principal and a report  $\hat{\theta}^A(\tilde{\theta}_j^A)$ ,  $j \in \{1, 2\}$  that the agent makes to the principal depending on the agent's report  $\tilde{\theta}_j^A$  to the collusion designer. By revelation principle we restrict attention to equilibria of the collusion subgame where the agent reports the truth to the collusion designer,  $\tilde{\theta}_j^A = \theta_j^A$ : reports are incentive compatible. Clearly if equilibrium transfers are such that  $\beta(\theta_1^A) \neq \beta(\theta_2^A)$  then the equilibrium of the collusion game is a separating one and the supervisor learns the agent's private information in the collusion subgame. Finally, collusion is a voluntary agreement, hence both parties will agree to participate in the collusion contract only if the allocation induced by the collusive agreement is individually rational. In our environment this implies that the allocation induced by the collusion game has to be strictly better than the allocation induced by the contracts offered by the principal if the parties decide not to participate in collusion.<sup>20</sup>

The enforceability of a side contract between two parties is an open issue in the literature on collusion. Often a long term relationship or a reputational argument is mentioned, in the background, to justify the enforceability of a side contract.<sup>21</sup> In our analysis we use a different

---

<sup>19</sup>See Felli (1990, Ch. 1) for a closely related model where collusion takes the form of take-it-or-leave-it offer from the agent to the supervisor.

<sup>20</sup>Recall our (standard) assumption that when indifferent the agent or the supervisor behaves in the way the principal wants them to behave. In other words, if indifferent neither party will participate in collusion.

<sup>21</sup>See Aghion and Caillaud (1988) for a paper that explicitly analyzes this long term relationship.

approach. We explicitly specify the penalty for breach, denoted  $\kappa$  ( $\kappa \geq 0$ ), that a party to collusion, typically the supervisor, has to pay to walk out of the collusive agreement. We also assume that a percentage  $\alpha$  ( $\alpha \in [0, 1]$ ), of this penalty is received by her counterpart, typically the agent. In other words, in the case of breach of the collusive agreement the payoff to the party breaching the side deal decreases by the amount  $\kappa$  while the payoff to the other party of the deal increases by the amount  $\alpha\kappa$ .

The existing literature has overlooked the principal's ability to prevent collusion by inducing parties to breach their collusive agreement. The difference between the penalty to the party breaching the collusion contract  $\kappa$  and the transfer to the other party  $\alpha\kappa$  is meant to capture the fact that most of the cost associated with breaching a side deal is associated with a loss of reputation and future opportunities. This implies that the cost cannot be easily transferred to one's counterpart in collusion. In other words, our general specification encompasses the situation in which *only* the supervisor incurs a loss when breaching the collusive contract ( $\alpha = 0$ ). Alternatively, our setup is also robust to considering situations in which the supervisor can walk away from the collusive contract just before it is signed (i.e. the cost for breaching the collusive contract is nil,  $\kappa = 0$ ).

The optimal mechanism we derive below works independently of the size of  $\kappa$ , this is meant to capture the fact that the loss in reputation associated with the breach may well exceed the financial benefits of the side deal. Notice that we are assuming that the precise value of  $\kappa$  is common knowledge to all parties.<sup>22</sup>

### 3.2. *Strongly Collusion Proof Contracts*

As mentioned above, in our setting collusive negotiation takes place between asymmetrically informed parties. This implies that in general the equilibrium outcome of the collusive game is not unique. Hence, the principal's objectives when facing the collusion problem are not at all obvious.

A possible objective might be for the principal to offer a contract to the supervisor and the agent such that when they get involved in the collusion game there exists at least one

---

<sup>22</sup>Clearly if the principal is not informed of the nature of the collusive contract and of the penalties associated with its breach a further level of complexity is added to the corresponding mechanism design problem. We leave the analysis of this setting to further research.

equilibrium of such a game in which no collusive agreement is enforced. We instead use a stronger notion of collusion-proofness in our analysis. This is defined as follows.

**Definition 1:** *A contract is strongly collusion-proof if the only equilibria of the collusion game between the parties involved are such that no collusive agreement is enforced and the equilibrium of the corresponding continuation game coincides with the equilibrium of the continuation game in a model where both the agent and the supervisor are honest.*<sup>23</sup>

### 3.3. Collusion under the honest contract

We begin by observing that the optimal *honest* contract presented in the previous section is not strongly collusion-proof. In other words, if the principal offers such a contract to both the supervisor and the agent, inequality (8) implies that in the event  $\theta^S = \theta_2^S$  the high productivity agent is willing to pay at most

$$b = w_{21} - w_{22} > 0 \tag{12}$$

to the supervisor for her to report  $\hat{\theta}_1^S$  while from equation (9) the low productivity agent is not willing to pay any positive amount to the supervisor for the same report. In the event  $\theta^S = \theta_1^S$ , instead, neither type of agent is willing to pay any amount to the supervisor for changing her report.

In other words, there exists a whole set of equilibria for the collusion game between the supervisor and the agent in which the supervisor observes the signal  $\theta_2^S$ , and the high productivity agent pays a positive bribe to the supervisor to induce him to report a low signal. These equilibria differ depending on the size of the transfer that the high productivity agent pays to the supervisor.

**Lemma 1:** *The honest contract is not strongly-collusion proof. Under the honest contract, when the supervisor observes the signal  $\theta_2^S$ , there exists a set of equilibria of the collusion game such that: the high productivity agent pays a positive bribe to the supervisor,  $\beta(\theta_2^A) \in (0, b)$ ,*

---

<sup>23</sup>In our environment the continuation game includes the revelation game in which both the agent and the supervisor report their private information to the principal, and the agent's subsequent decision of how much effort to exert. The requirement that the equilibrium of the continuation game coincides with that of the model where agent and supervisor are honest is introduced so as to rule out situations in which the agent and the supervisor do not reach any collusive agreement but the information revealed by the agent during the collusion negotiation induces the supervisor to behave in a different way from how she would have behaved if she were honest.

the supervisor reports  $\hat{\theta}^S(\theta_2^A) = \hat{\theta}_1^S$  while the agent reports  $\hat{\theta}^A(\theta_2^A) = \theta_2^A$ . The collusion designer prescribes  $\beta(\theta_1^A) = 0$ ,  $\hat{\theta}^S(\theta_1^A) = \hat{\theta}_2^S$  and  $\hat{\theta}^A(\theta_1^A) = \theta_1^A$  for the low productivity agent that does not participate in collusion.

This result shows that the supervisor and the agent may successfully engage in collusion when the *honest* contract is offered to them. It is critical for our analysis that all the equilibria of the collusion game characterized in Lemma 1 above are separating equilibria:  $\beta(\theta_2^A) > \beta(\theta_1^A) = 0$ . In other words, the high productivity agent reveals his type by participating in collusion and making a positive transfer to the supervisor while the low productivity agent does not. This implies that, in spite of the asymmetry of information that characterizes the collusive negotiation, the supervisor, by observing the agent's willingness to participate in collusion, learns the exact value of the productivity of the agent. In other words, the existence of collusion is synonymous with the agent having high productivity.

## 4. The Collusion-Proof Optimal Mechanism

### 4.1. Preamble

In this section we propose a mechanism which allows the principal to prevent collusion between the supervisor and the agent in a costless way: in this mechanism the principal allows the supervisor to blow the whistle by reporting that a collusion agreement has been reached. This report is associated with a premium that the principal pays the supervisor which covers the penalty the supervisor has to pay for breaching the collusive agreement. We now show that such a promise does not involve any extra cost for the principal: it is never carried out in equilibrium. If the high productivity agent observes this clause of the employment contract of the supervisor, he never agrees to participate in collusion as by doing so he loses the informational rent that he otherwise would have gained.

### 4.2. Candidate to Strongly Collusion-Proof Contract

When the *honest* contract is in place, the supervisor may observe two different signals of the agent's productivity: the standard signal  $\theta^S \in \Theta^S$  and the information possibly leaked during the collusion game. The latter takes the form of the agent's truthful report in the collusion game, which, under the *honest* contract, fully reveals the productivity of the agent.

It is critical for the construction of the collusion-proof contract (contract *CP*) to enlarge the message space of the supervisor. This should allow her to report to the principal that

the agent has high productivity with certainty once she sees the agent's optimal strategy in the collusion game:  $\Theta^S \cup \{\ell_2^A\}$ , where  $\ell_2^A$  denotes the leaked information during the collusive game (in equilibrium this will be interpreted as the agent having high productivity). As with every other message,  $\ell_2^A$  is soft or unverifiable information so it is possible that  $\ell_2^A \neq \theta_2^A$ . The message space of the agent is for the moment left unmodified.

We now specify the part of the strongly collusion-proof candidate contract  $CP$  that concerns the employment contract of the agent:  $CP^A$ . If the supervisor reports any of the messages in  $\Theta^S$  and the agent reports any of the messages in  $\Theta^A$  the agent's payoffs are, as in the *honest* contract, characterized by the solution to Problem (6). If the supervisor reports the new message  $\ell_2^A$ , and the agent reports  $\hat{\theta}_2^A$  we assume that the agent is asked to produce output  $x_2$ , defined in equation (7), and is paid a wage  $\hat{w}$  so that:

$$\hat{w} = \bar{w} - \kappa + d(x_2 - \theta_2^A) \quad (13)$$

where  $\bar{w}$  is the reservation utility,  $\kappa$  the penalty the supervisor pays to breach the collusive agreement, and  $d(x_2 - \theta_2^A)$  is his disutility of effort.

The same remuneration  $\hat{w}$  applies to the agent if the supervisor reports  $\ell_2^A$  and the agent reports  $\hat{\theta}_1^A$ . Also in this case the agent is asked to produce output  $x_2$ .

We now characterize the collusion-proof candidate contract between the principal and the supervisor:  $CP^S$ . If the supervisor reports any of the signals in  $\Theta^S$  she is paid her constant reservation wage  $\bar{s}$ , as in equation (5), whatever the agent's strategy choice.

If the supervisor reports the message  $\ell_2^A$  and the agent reports  $\hat{\theta}_2^A$  the supervisor gets her reservation salary plus a premium equal to the penalty  $\kappa$  which she has to pay to breach the collusive agreement and report  $\ell_2^A$  to the principal:

$$s(\ell_2^A, \hat{\theta}_2^A) = \bar{s} + \kappa, \quad (14)$$

A's report \ S's report	$\hat{\theta}_1^A$	$\hat{\theta}_2^A$
$\ell_2^A$	$CP^S = [\bar{s} - \gamma]$ $CP^A = [\hat{w}, x_2]$	$CP^S = [\bar{s} + \kappa]$ $CP^A = [\hat{w}, x_2]$
$\hat{\theta}_1^S$	$CP^S = [\bar{s}]$ $CP^A = [w_{11}, x_{11}]$	$CP^S = [\bar{s}]$ $CP^A = [w_{21}, x_{21}]$
$\hat{\theta}_2^S$	$CP^S = [\bar{s}]$ $CP^A = [w_{12}, x_{12}]$	$CP^S = [\bar{s}]$ $CP^A = [w_{22}, x_{22}]$

Table1: Collusion-Proof Contract  $CP$ .

Finally, if the supervisor reports  $\ell_2^A$  and the agent, reports  $\hat{\theta}_1^A$  the supervisor receives her reservation salary minus a positive punishment  $\gamma$ .

$$s(\ell_2^A, \hat{\theta}_1^A) = \bar{s} - \gamma, \quad \gamma > 0 \quad (15)$$

We impose a constraint on the size of the punishment  $\gamma$  so as to prevent the supervisor from reporting  $\ell_2^A$  if the agent does not engage in collusion.

$$p_2 V(\bar{s} - \gamma) + (1 - p_2) V(\bar{s} + \kappa) = V(\bar{s}) \quad (16)$$

Condition (16) implies that after observing the signal  $\theta_1^S$

$$p_1 V(\bar{s} - \gamma) + (1 - p_1) V(\bar{s} + \kappa) < V(\bar{s}) \quad (17)$$

Table 1 above summarizes the description of the candidate collusion-proof contract  $CP$ .

Finally, recall that if we interpret the supervisor's message  $\ell_2^A$  as informing the principal that collusion occurred then  $\ell_2^A$  is equivalent to the supervisor blowing the whistle on the existence of collusion.

### 4.3. Preventing Collusion

We can now show that the collusion agreement we presented in Lemma 1 above cannot occur in any equilibrium of the supervisor and agent subgame under contract  $CP$ .

Assume that the principal offers the contract  $CP$  to both the supervisor and the agent and that they both observe the signal  $\theta_2^S$ .

**Proposition 2:** *There exists no equilibrium collusive agreement such that the supervisor, after observing the signal  $\theta_2^S$ , reports  $\hat{\theta}^S(\theta_2^A) = \hat{\theta}_1^S$  while the  $\theta_2^A$  agent makes a transfer  $\beta(\theta_2^A) \in (0, b)$  and reports  $\hat{\theta}^A(\theta_2^A) = \theta_2^A$ .*

The main intuition behind this result is as follows. Notice first that Lemma 1 implies that all collusive agreements between the supervisor and the agent under the *honest* contract lead to separating equilibria and hence leak the true type of the agent to the supervisor. Moreover, contract  $CP$  specifies payments to both the supervisor and the agent that coincide with the *honest* contract whenever the supervisor reports  $\hat{\theta}^S \in \{\theta_1^S, \theta_2^S\}$ . However, contract  $CP$  also offers to the supervisor that engaged in collusion the option to breach the collusive agreement at no cost if the supervisor is certain that the agent is high productivity and reports  $\ell_2^A$  to the principal. In the latter case the supervisor payoff is  $\bar{s} + \beta(\theta_2^A)$  which coincides with her payoff if she goes along with collusion.<sup>24</sup> The result is that the supervisor is always compensated for breaching the collusion agreement contract. She is thus indifferent and reports  $\ell_2^A$  to the principal. According to contract  $CP$  the high productivity agent is then strictly better off by not engaging in collusion.

---

<sup>24</sup>Recall that bribes are paid upfront and are not refundable. Notice, however, that  $\alpha\kappa$ , what the agent receives in the event of a breach of the collusive contract on the part of the supervisor, may well exceed the bribe paid upfront and hence be regarded as a refund of this bribe in the event of a breach.

The key observation is that in our framework the equilibria of the collusion game between the supervisor and the agent are separating ones, which by their own nature reveal the exact productivity of the agent to the supervisor. Hence, giving the supervisor the discretionary power to report this leaked information to the principal destroys these separating equilibria. Clearly, the same mechanism would not be so successful in a model in which pooling as well as separating equilibria of the collusion game might arise. However, a mechanism similar to  $CP$  would still be of use to the principal even in a framework in which there exists pooling equilibria of collusive negotiation. Pooling equilibria of the collusion game need to specify transfers  $\beta(\theta_1^A) = \beta(\theta_2^A)$  that are not higher than the minimum willingness to pay the two types of agent for the report of the supervisor. Therefore such a mechanism would reduce the costs necessary to prevent collusion. Costly resources would be needed only to get rid of the pooling equilibria of the collusion game — these are the cheaper equilibria to prevent using a mechanism à la Laffont and Martimort (1997) — while the more expensive separating equilibria of the collusion game could still be costlessly eliminated as in  $CP$ .<sup>25</sup>

Notice that the existence of any level of asymmetric information is enough for  $CP$  to be successful in eliminating "some" collusion. Indeed,  $CP$  prevents the collusive agreement in Lemma 1 from arising in equilibrium whatever the precision of the signal  $\theta_2^S$  with the exception of the limit case  $q_1 = 1$ , that is when the supervisor is perfectly informed after observing a high signal. The following result identifies the situations in which our result on collusion-proofness holds.

**Corollary 1:** *No equilibrium collusive agreement, as in Lemma 1, exists for any imperfect signal  $\theta_2^S$  observed by the supervisor:  $(1 - p_2) < 1$ .*

This result implies that the costs of preventing collusion are discontinuous in the limit as the noise associated with the signal observed by the supervisor vanishes. When the supervisor's signal is perfect, preventing collusion becomes costly for the principal as in Laffont and Martimort (1997). The supervisor and the agent collude only when the supervisor perfectly observes the productivity of the agent. The mechanism  $CP$  is then of no use to the principal.

---

<sup>25</sup>Notice that similar considerations also apply when the supervisor has "hard" information as in Tirole (1986). Indeed, in this case collusion only occurs between symmetrically informed parties, hence costly resources need to be used to prevent collusion arising in equilibrium.

It is worth observing that the mechanism we described in contract  $CP$  allows the principal to prevent collusion in a costless way when the signal  $\theta_1^S$  is a perfect signal: when  $q_2$  converges to zero, or equivalently  $p_1$  converges to one. Collusion occurs only when both the supervisor and the agent observe the signal  $\theta_2^S$ , which is not a perfect signal: the probability that the agent has low productivity is not null,  $p_2 > 0$ .<sup>26</sup> This implies that the collusion game can still reveal some information to the supervisor. Therefore contract  $CP$  is still effective in preventing (separating) collusion agreements between the supervisor and the agent at no additional costs for the principal (the proof of Proposition 2 applies).

A final observation concerns the willingness of the principal to use a supervisor. Since the solution to the collusion problem we propose is costless for the principal, the same considerations we presented at the end of Subsection 2.4 apply in this case. There exist values of the reservation salary of the supervisor for which the principal has a strictly positive gain by hiring her.

## 5. Blackmail

### 5.1. The Blackmail Threat

A different type of manipulation may occur when the principal offers the contract  $CP$  to both the supervisor and the agent. This takes the form of *blackmail*.

Blackmail is a unilateral threat by one of the parties involved. For blackmail to occur in equilibrium we require the threat to be credible. In other words, an equilibrium of our model with blackmail is a PBE where the blackmailing party asks for a transfer  $\mu > 0$  from the blackmailed party. If the transfer is made then the blackmailing party complies with the equilibrium strategy in the absence of blackmail. If the blackmailed party refuses to make the transfer the blackmailing party behaves consistently with his/her threat.

In what follows we show that allowing the supervisor to report the information leaked during the collusion game to the principal provides the supervisor with the opportunity to

---

<sup>26</sup>Notice that if  $\theta_1^S$  is a perfect signal, collusion between the supervisor and the agent will take a slightly different form even when the *honest* contract is offered. In fact, in such a case there will be no need for the principal to specify a payoff for the high productivity agent if the supervisor reports  $\hat{\theta}_1^S$ : the signal is perfect, so, provided the supervisor reports the truth, the agent's productivity is certainly low. However, it is still profitable for the high productivity agent to bribe the supervisor to report signal  $\hat{\theta}_1^S$  when  $\theta_2^S$  is observed but this report requires the agent to report  $\hat{\theta}_1^A$  or, equivalently, to produce a low output. Indeed, the premium the high productivity agent receives in this way is greater than the informational rent he would get if the supervisor reports the truth.

threaten the agent to report  $\ell_2^A$ , even in the absence of any collusion, unless she receives a payment  $\mu$  on the part of the agent.

Assume that the principal offers the contract  $CP$  to both the supervisor and the agent and they both accept. As from Proposition 2, whatever the signal  $\theta_i^S$ , the agent refuses to participate in any collusive agreement with the supervisor. Assume now that, before reporting its observed signal, the supervisor threaten the agent to report the signal  $\ell_2^A$  unless she receives a strictly positive payment  $\mu > 0$ . We show below that there exist values of  $\mu$  that render this blackmail a credible threat on the part of the supervisor.

Notice first that since no collusion took place, following this threat, if both types of agent behave in the same way, the supervisor is still uninformed on the value of the agent's type  $\theta_i^A$ . Therefore, equations (16) and (17) guarantee that under contract  $CP$  if both types of agent refuse or accept to pay  $\mu$  the supervisor reports  $\theta_i^S$  rather than  $\ell_2^A$ . In other words the blackmail threat is not credible.

This means that blackmail can be credible only if the two types of agent make different choices when deciding whether or not to succumb to blackmail. We, then, need to consider each type of agent's willingness to go along with the supervisor's blackmail threat.

Consider first the  $\theta_2^A$  agent. His maximum willingness to pay to avoid the supervisor reporting the message  $\ell_2^A$  is given by the difference between his payoff if the supervisor reports the signal  $\theta_i^S$  and his payoff when she reports  $\ell_2^A$ . This difference is

$$\mathcal{W}_2^A = \kappa + d(x_{1i} - \theta_1^A) - d(x_{1i} - \theta_2^A) \quad (18)$$

Consider now the  $\theta_1^A$  agent. His maximum willingness to pay is instead

$$\mathcal{W}_1^A = \kappa + d(x_2 - \theta_1^A) - d(x_2 - \theta_2^A) \quad (19)$$

It then follows from the convexity of the disutility of effort,  $d''(\cdot) > 0$ , and  $x_2 > x_{1i}$  that the  $\theta_1^A$  agent is willing to pay strictly more than the  $\theta_2^A$  agent to avoid the supervisor reporting  $\ell_2^A$  rather than  $\theta_i^S$ .

$$\mathcal{W}_1^A > \mathcal{W}_2^A \quad (20)$$

This implies that the only blackmail payment  $\mu$  that separates the two types of agent is one

that is acceptable to the  $\theta_1^A$  agent but not acceptable to a  $\theta_2^A$  agent:

$$\mathcal{W}_1^A > \mu > \mathcal{W}_2^A \quad (21)$$

Any other value of  $\mu$  is either acceptable to both types of agent or not acceptable to either type.

Notice now that if the supervisor blackmails the agent by asking for a transfer  $\mu$  satisfying (21) above the supervisor, following the agent decision to pay or not  $\mu$ , discovers the type of the agent. In particular, following the agent's decision not to pay  $\mu$ , the supervisor knows that the agent is of type  $\theta_2^A$ . It is then optimal for the supervisor to report  $\ell_2^A$  since in so doing she gets payoff  $\bar{s} + \kappa$  rather than the payoff  $\bar{s}$  she gets from reporting  $\theta_i^S$ . On the other hand, following the agent's decision to pay  $\mu$  the supervisor knows that the agent is of type  $\theta_1^A$ . It is then optimal for the superior to report the signal  $\theta_i^S$  since in so doing she gets from the principal  $\bar{s}$  instead of  $\bar{s} - \gamma$  as from contract  $CP$ . In other words, the supervisor's blackmail threat is credible.

**Lemma 2:** *The contract  $CP$  is vulnerable to blackmail. Under contract  $CP$  there exists a set of equilibria such that if both types of agent and the supervisor accept the contract  $CP$  the supervisor credibly threaten the agent to report  $\ell_2^A$  unless a transfer  $\mu > 0$  satisfying (21), is paid by the agent to the supervisor. ■*

As in the case of collusion, the reason why the supervisor's blackmail is credible is that if blackmail occurs it separates the two types of agents and, as a consequence, the supervisor discovers the type of the agent and finds it optimal to behave differently depending on whether the agent accepts or not to pay the transfer  $\mu$ .

### 5.2. Preventing Collusion and Blackmail

We propose here a mechanism that prevents both collusion and blackmail. Similarly to contract  $CP$ , this mechanism enlarges the supervisor's message space allowing her to report the message  $\ell_2^A$ . Additionally, this mechanism now also allows the agent to blow the whistle by enlarging his message space and allowing him to report whether he received a blackmail threat from the supervisor. We denote the latter message  $\mathcal{B}$ . We first define what it means for a contract to be *blackmail-proof*.

**Definition 2:** A contract is *blackmail-proof* if all PBE of the model are such that no party can credibly threaten any other party to deviate from the prescribed equilibrium behavior in the absence of blackmail in exchange for a transfer  $\mu > 0$ .<sup>27</sup>

A's report		$\hat{\theta}_1^A$	$\hat{\theta}_2^A$	$\mathcal{B}$
S's report				
$\ell_2^A$		$CBP^S = [\bar{s} - \gamma]$ $CBP^A = [\hat{w}, x_2]$	$CBP^S = [\bar{s} + \kappa]$ $CBP^A = [\hat{w}, x_2]$	$CBP^S = [\bar{s} - \varepsilon]$ $CBP^A = [\hat{w}, x_2]$
$\hat{\theta}_1^S$		$CBP^S = [\bar{s}]$ $CBP^A = [w_{11}, x_{11}]$	$CBP^S = [\bar{s}]$ $CBP^A = [w_{21}, x_{21}]$	
$\hat{\theta}_2^S$		$CBP^S = [\bar{s}]$ $CBP^A = [w_{12}, x_{12}]$	$CBP^S = [\bar{s}]$ $CBP^A = [w_{22}, x_{22}]$	

Table 2: Collusion and Blackmail-Proof Contract  $CBP$ .

The mechanism we propose, denoted  $CBP$  and summarized in the Table 2 above, allows the principal to prevent, costlessly, both collusion and blackmail.

The contract  $CBP$  enlarges the message space of both the supervisor and the agent by allowing both to blow the whistle. It not only allows the supervisor to report the message  $\ell_2^A$  if collusion occurs, but also allows the agent to report to the principal that blackmail occurred, message  $\mathcal{B}$ , and in so doing triggers a penalty for the supervisor that discourages her from blackmailing the agent.

<sup>27</sup>Recall that in our model we assume that when indifferent, a party complies with the strategy desired by the principal, hence blackmail is not credible if, in the subgame following the blackmailed party decision to not pay  $\mu$ , the blackmailing party is indifferent to complying or not with the blackmail threat.

Following the supervisor's report  $\ell_2^A$ , we allow the agent to report either his type  $\hat{\theta}_i^A$  or the additional message  $\mathcal{B}$ . Notice that we restrict the agent to report the additional message  $\mathcal{B}$  only after the supervisor's report of the leaked information  $\ell_2^A$  in order to prevent additional opportunities for manipulation of the optimal mechanism on both the part of the supervisor and the agent.

In case the agent reports  $\mathcal{B}$  the supervisor's remuneration is  $\bar{s} - \varepsilon$ , where  $\varepsilon > 0$  is an arbitrary small number, while the agent is asked to produce output  $x_2$ , defined in equation (7) above, and is paid a wage  $\hat{w}$  defined in equation (13). In other words, the agent is indifferent between reporting any of the messages in  $(\hat{\theta}_1^A, \hat{\theta}_2^A)$  and  $\mathcal{B}$  while the supervisor, if she does not know the type of the agent, is strictly worse off when the agent reports  $\mathcal{B}$ .

We are now in a position to show that if the principal offers contract  $CBP$  to both the supervisor and the agent and this contract is accepted, no collusion or blackmail takes place and the outcome coincides, on the equilibrium path, with the *honest* contract above.

**Proposition 3:** *The contract  $CBP$  is strongly collusion-proof and it is not liable for any form of blackmail either on the part of the superior or the agent. The PBE of the continuation game between the supervisor and the agent coincides with the PBE of the corresponding continuation game under the *honest* contract (Proposition 1).*

Intuitively, under contract  $CBP$  following the supervisor's threat to report  $\ell_2^A$  unless she receives a transfer  $\mu$  satisfying (21), the agent when deciding which message to report will be indifferent, whatever the report of the supervisor is (and regardless of whether the agent accepted or refused to pay  $\mu$ ). Therefore the agent will report the truth, that is the message  $\mathcal{B}$ . This implies that the supervisor is strictly worse off by blackmailing the agent (her payoff is  $\bar{s} - \varepsilon$ ) rather than not engaging in any threat (her payoff is  $\bar{s}$ ). In the proof we also show that the message  $\mathcal{B}$  does not introduce new opportunities for both the supervisor or the agent to engage in collusion. It also avoids opportunities for the agent to threaten the supervisor with the additional message  $\mathcal{B}$ .

## 6. Concluding Remarks

In this paper we have showed that potential collusion between the intermediate and bottom layers of an organization might make it desirable for the principal to allow intermediate layers to blow the whistle. In other words, the principal, allowing the supervisor to blow the

whistle on whether collusion occurred, aligns the objectives of the supervisor with her own and eliminates the opportunity of collusive behavior between layers and, ultimately, enhances efficiency.

On the other hand, allowing the supervisor to report that collusion has occurred introduces into the organizational structure the opportunity for the supervisor to blackmail the agent. Once again, allowing the agent to blow the whistle on the existence of blackmail prevents any wrongdoing in the organization and replicates the honest outcome.

At the core of our argument is that in many collusive agreements some information is shared between collusive parties and this information can subsequently be used to the detriment of a collusive party. In such circumstances the principal (residual claimant in our setting) could appropriately reward the leaking of such information and in this manner avoid collusive agreements between his employees.

In principle, one could apply this same logic to the contract the principal writes with the agent. Indeed, the direct mechanism we have analyzed specifies that the agent and supervisor report their private information to the principal and only at a later stage can the agent exert her productive effort. In principle, one could argue that the principal could use the information revealed by the agent and renege on the promised output-contingent remuneration before output is realized. Notice however, that this multistage performance on the part of the agent only applies to the direct revelation mechanism. The most obvious indirect mechanism would have the agent, after the supervisor's report, exert a productive effort that leads to the observed output. In other words, the agent's private information is only revealed when production is completed. Assuming that the principal can renege on a promise at this stage would be equivalent to assuming that simple trade cannot be enforced. This lack of commitment clearly opens up further sources of inefficiency in usual contracting environments that are beyond the scope of this paper. We should add, that it is sensible to assume that contracts written by the principal can be enforced by a Court of Law while the same cannot be said of side contracts. Our paper should then be read as a first step in the direction of explicitly allowing contracting parties to breach their signed agreements.

Finally, our analysis sheds light on the use of rules versus discretion in the designing of the optimal degree of decision power of members of an organization. Tirole (1986) argues that fixed rules as opposed to discretion might be used to reduce patterns of collusive behavior in

large organizations. In this paper we show that whenever collusion takes place in conditions of asymmetric information, an increase in the discretionary power (the message space) of intermediate layers of the organization, as opposed to fixed rules, may have a beneficial effect in reducing the possibility of both collusion and blackmail.

The results presented in this paper can be interpreted as a way to implement a particular outcome that enlarges the strategy space of subordinates. The basic intuition is as follows.<sup>28</sup> We have learned from the literature on commitment that under certain conditions a player can increase his welfare whilst restricting, in a credible way, his choices: his strategy space.<sup>29</sup> This paper complements this literature by showing that enlarging the strategy space of a subordinate may help the residual claimant of an organization to enhance his own welfare, whilst reducing the welfare of his subordinate.

## Appendix

**Proof of Lemma 1:** Assume that the *honest* contract binds the principal, the supervisor and the agent. Assume that  $S$  observes the signal  $\theta_2^S$ . The collusion contracts  $\mathcal{C} = \{\beta(\theta_1^A), \beta(\theta_2^A); \hat{\theta}^S(\theta_2^A) = \hat{\theta}_1^S, \hat{\theta}^S(\theta_1^A) = \hat{\theta}_2^S\}$ , such that  $\beta(\theta_1^A) = 0$ ,  $\beta(\theta_2^A) \in (0, b)$  — with  $b$  as in equation (12) — and  $S$  reports  $\hat{\theta}_1^S$  if the agent reports  $\theta_2^A$  to the collusion designer and  $\hat{\theta}_2^S$  if the agent reports  $\theta_1^A$  to the collusion designer, satisfies the collusion-game incentive compatibility and individual rationality constraints for the  $\theta_2^A$  agent but does not satisfy the collusion-game individual rationality constraint for the  $\theta_1^A$  agent.

Consider first the collusion game incentive compatibility constraint for the  $\theta_2^A$  agent

$$w_{21} - \beta(\theta_2^A) - d(x_2 - \theta_2^A) \geq w_{12} - \beta(\theta_1^A) - d(x_{12} - \theta_2^A) = w_{22} - \beta(\theta_1^A) - d(x_2 - \theta_2^A) \quad (\text{A.1})$$

Equations (8), (12),  $0 < \beta(\theta_2^A) < b$  and  $\beta(\theta_1^A) = 0$  imply that (A.1) holds with a strict inequality.<sup>30</sup> Consider now the collusion-game individual rationality constraint for the  $\theta_2^A$  agent:

$$w_{21} - \beta(\theta_2^A) - d(x_2 - \theta_2^A) \geq w_{22} - d(x_2 - \theta_2^A) \quad (\text{A.2})$$

Equations (8), (12) and  $0 < \beta(\theta_2^A) < b$  imply that (A.2) also holds with a strict inequality. The collusion-game

---

<sup>28</sup>We are indebted to David Canning for this intuition.

<sup>29</sup>See for example Laffont and Tirole (1988).

<sup>30</sup>Notice that equation (11) and  $\beta(\theta_1^A) = 0$  imply that, following the deviation of the  $\theta_2^A$  agent in the report to the collusion designer, this agent will be indifferent when making his report to the principal and hence will report the truth.

individual rationality constraint for the  $\theta_1^A$  agent is instead:

$$w_{12} - \beta(\theta_1^A) - d(x_{12} - \theta_1^A) \geq w_{12} - d(x_{12} - \theta_1^A) \quad (\text{A.3})$$

From  $\beta(\theta_1^A) = 0$  it follows that (A.3) holds with equality. This means that the  $\theta_1^A$  agent does not participate in the collusion game since, when indifferent, the agent does what the principal would like him to do.<sup>31</sup>

Consider now the supervisor's collusion-game individual rationality constraint associated with the collusion contract  $\mathcal{C}$ . This is:

$$\nu V(\bar{s}) + (1 - \nu)V(\bar{s} + \beta(\theta_2^A)) \geq V(\bar{s}) \quad (\text{A.4})$$

where  $\nu$  denotes the supervisor's beliefs at the collusion stage that the type of the agent is  $\theta_1^A$ . Clearly, if  $\nu < 1$  and  $\beta(\theta_2^A) > 0$  constraint (A.4) is satisfied with a strict inequality. In other words, under the *honest* contract it is an equilibrium of the collusion game for both the type  $\theta_2^A$  agent and the supervisor to accept any of the collusion contracts  $\mathcal{C}$ . ■

**Proof of Proposition 2:** Assume that the supervisor observes the signal  $\theta_2^S$ . Consider any incentive compatible collusive contract such that the supervisor reports  $\theta^S(\theta_2^A) = \hat{\theta}_1^S$  and the  $\theta_2^A$  agent pays the bribe  $\beta(\theta_2^A) \in (0, b)$ , as in equation (12). We proceed in four steps.

**Step 1:** *The agent always reports the truth to the principal whatever his productivity and the outcome of the collusion game.*

We start from the high productivity agent. Assume that the  $\theta_2^A$  agent participates in collusion and the collusion contract is not breached by the supervisor this agent's payoff is then either  $w_{21} - \beta(\theta_2^A) - d(x_2 - \theta_2^A)$ , if he reports the truth, or  $w_{11} - \beta(\theta_2^A) - d(x_{11} - \theta_2^A)$ , if he does not. Equation (10) implies that the agent is indifferent between these two payoffs, hence he reports the truth. Assume next that the  $\theta_2^A$  agent participates in collusion and the collusion contract is breached by the supervisor who reports the message  $\ell_2^A$ . This agent's payoff is then  $\hat{w} - \beta(\theta_2^A) + \alpha\kappa - d(x_2 - \theta_2^A) = \bar{w} - \beta(\theta_2^A) - (1 - \alpha)\kappa$  whether he reports the truth or he does not. Hence, the agent, being indifferent, reports the truth.

Assume now that the  $\theta_2^A$  agent does not participate in collusion. If the supervisor reports the observed signal  $\theta_2^S$ , the binding incentive compatibility constraint for the high productivity agent, equation (11), implies that the agent reports the truth. If instead the supervisor reports the additional signal  $\ell_2^A$  the agent's payoff is  $\hat{w} - d(x_2 - \theta_2^A) = \bar{w} - \kappa$  whether he reports the truth or he does not. Hence, the high productivity agent is indifferent and reports the truth.

Consider, now, the low productivity agent. Assume that the  $\theta_1^A$  agent participates in collusion and the supervisor does not breach the collusive agreement and reports the signal  $\hat{\theta}_1^S$ , the agent's payoff is  $\bar{w} - \beta(\theta_1^A)$  if he reports  $\hat{\theta}_1^A$  and  $w_{21} - \beta(\theta_1^A) - d(x_2 - \theta_1^A) < \bar{w} - \beta(\theta_1^A)$  if he reports  $\hat{\theta}_2^A$ . Hence the agent will report

---

<sup>31</sup>Notice that a similar argument shows that neither the  $\theta_1^A$  agent nor the  $\theta_2^A$  participate in collusion if the contract  $\mathcal{C}$  is such that  $\beta(\theta_2^A) = b$ .

the truth. Conversely, assume that the  $\theta_1^A$  agent does not participate in collusion and the supervisor reports the observed signal  $\hat{\theta}_2^S$ . The incentive compatibility constraint for the low productivity agent — implied by  $\theta_2^A > \theta_1^A$  and equation (11) — holds with strict inequality, hence the agent reports the truth.

Finally, assume the supervisor reports the message  $\ell_2^A$ , the agent's payoff is the same whatever his report. It is either  $\hat{w} - \beta(\theta_1^A) + \alpha\kappa - d(x_2 - \theta_1^A) = \bar{w} - \beta(\theta_1^A) - (1 - \alpha)\kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A)$ , if the supervisor participated in collusion, breaches the collusion contract and reports the message  $\ell_2^A$  or is  $\hat{w} - d(x_2 - \theta_1^A) = \bar{w} - \kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A)$  if she reports the message  $\ell_2^A$  without participating in collusion. Either case, the agent, being indifferent, reports the truth.

**Step 2:** *Derivation of the supervisor's best response when the supervisor observes  $\theta_2^S$ .*

As above, denote  $\nu$  the supervisor's belief that the agent is of type  $\theta_1^A$  at the collusion stage. Assume, first, that both the agent and the supervisor accept to participate in collusion. The supervisor's payoff is then  $V(\bar{s} + \beta(\theta_2^A))$  if she complies with the collusion contract and reports  $\theta^S(\theta_2^A) = \hat{\theta}_1^S$ . The supervisor expected payoff is instead  $\nu V(\bar{s} + \beta(\theta_2^A) - \gamma - \kappa) + (1 - \nu)V(\bar{s} + \beta(\theta_2^A))$  if she breaches the collusion contract and reports the additional signal  $\ell_2^A$ . Equation (14) implies that if  $\nu > 0$  the former option yields a higher payoff to the supervisor, hence she will comply with the collusion contract. If, instead,  $\nu = 0$  the supervisor is indifferent between the two options, hence she acts in the way most preferred by the principal: she breaches the collusion contract and reports the signal  $\ell_2^A$  to the principal.

Consider now the supervisor decision whether to participate in the collusion game. As seen above her payoff, whether she breaches the collusion contract or not, is  $V(\bar{s} + \beta(\theta_2^A))$  while her payoff is  $V(\bar{s})$  if she refuses to participate in the collusion game and reports the observed signal  $\hat{\theta}_2^S$ . Clearly, if  $\beta(\theta_2^A) > 0$  the supervisor is better off accepting to participate in collusion. Only if  $\beta(\theta_2^A) = 0$  the supervisor is indifferent and refuses to participate in the collusion game.

**Step 3:** *The value of the supervisor's belief  $\nu = 0$  is the only one consistent with the low productivity agent's behavior.*

Assume  $\nu > 0$  and consider the behavior of the low productivity agent. Given the supervisor's best response (Step 2) the agent's payoff is either  $\bar{w} - \beta(\theta_1^A)$ , if he participates in the collusion game, or  $\bar{w}$ , if he does not. Clearly the low productivity agent always refuses to participate in the collusion game for  $\beta(\theta_1^A) \geq 0$ . This contradicts the hypothesis  $\nu > 0$ .

**Step 4:** *The agent always refuses to participate in the collusion game whatever his productivity.*

We start from the low productivity agent. Given Step 2 and 3, the agent's payoff is  $\hat{w} + \alpha\kappa - d(x_2 - \theta_1^A) = \bar{w} - (1 - \alpha)\kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A)$  if he participates in the collusion game and produces output  $x_2$ . Such payoff is strictly lower than the agent's reservation wage  $\bar{w}$  since  $\theta_1^A < \theta_2^A$ . Conversely, if the agent refuses to participate in the collusion game his payoff is  $\bar{w}$ , by equation (9). Hence, the low productivity agent refuses to participate in the collusion game.

Finally, consider the high productivity agent. Steps 1, 2 and 3 imply that if he accepts the collusive offer his payoff is  $\hat{w} - \beta(\theta_2^A) + \alpha\kappa - d(x_2 - \theta_2^A) = \bar{w} - \beta(\theta_2^A) - (1 - \alpha)\kappa$ . Conversely, if he rejects the collusive offer his payoff is  $w_{22} - d(x_{22} - \theta_2^A)$  which, by equation (8), is strictly greater than  $\bar{w} - \beta(\theta_2^A) - (1 - \alpha)\kappa$ . Hence, the high productivity agent refuses to participate in the collusion game. ■

**Proof of Corollary 1:** The proof follows immediately from the observation that the proof of Proposition 2 does not rely on how precise the signal  $\theta_2^S$  is of the agent being of type  $\theta_2^A$  but only on whether, having observed signal  $\theta_2^S$  there still exists a residual, strictly positive, probability that the agent is of type  $\theta_1^A$ . ■

Proposition 3 will be proved with the assistance of the following four lemmas:

**Lemma A.1:** *The contract CBP is such that, in the absence of collusion, any blackmail threat on the part of S is not credible.*

**Proof:** Assume  $S$  threatens  $A$  to report  $\ell_2^A$  unless she receives a transfer  $\mu > 0$  from  $A$ .

Notice, first, that following  $S$ 's report  $\ell_2^A$ ,  $A$  is indifferent and hence he reports  $\mathcal{B}$  to  $P$ .

Assume now that while the type  $\theta_1^A$  of  $A$  pays  $\mu > 0$  type  $\theta_2^A$  of  $A$  does not. Following  $A$ 's decision not to pay,  $S$ 's payoff is  $V(\bar{s} - \varepsilon)$  if  $S$  reports  $\ell_2^A$  and  $V(\bar{s})$  if  $S$  reports  $\theta_i^S$ . Therefore,  $S$  reports  $\theta_i^S$  and hence  $S$ 's threat is not credible.

Assume now that while the type  $\theta_1^A$  of  $A$  does not pay  $\mu > 0$  type  $\theta_2^A$  of  $A$  does. Following  $A$ 's decision not to pay,  $S$ 's payoff is  $V(\bar{s} - \varepsilon)$  if  $S$  reports  $\ell_2^A$  and  $V(\bar{s})$  if  $S$  reports  $\theta_i^S$ . Once again,  $S$  reports  $\theta_i^S$  and hence  $S$ 's threat is not credible.

Assume now that both types of  $A$  pay  $\mu > 0$ . Following type  $\theta_2^A$  of  $A$ 's deviation: not to pay,  $S$ 's payoff is  $V(\bar{s} - \varepsilon)$  if  $S$  reports  $\ell_2^A$  and  $V(\bar{s})$  if  $S$  reports  $\theta_i^S$  whatever  $S$ 's beliefs. Once again,  $S$  reports  $\theta_i^S$  and hence  $S$ 's threat is not credible.

Finally, consider the case where both types of  $A$  do not pay  $\mu > 0$ .  $S$ 's payoff is  $V(\bar{s} - \varepsilon)$  if  $S$  reports  $\ell_2^A$  and  $V(\bar{s})$  if  $S$  reports  $\theta_i^S$ . In other words,  $S$  reports  $\theta_i^S$  and  $S$ 's threat is not credible. ■

**Lemma A.2:** *The contract CBP is such that, in the absence of collusion, any blackmail threat on the part of A is not credible.*

**Proof:** Assume that, in the absence of any threat on the part of  $S$ ,  $A$  threatens  $S$  to report  $\mathcal{B}$  following  $S$ 's report  $\ell_2^A$  unless he receives a transfer  $\eta > 0$  from  $S$ .

Consider first the case in which the type  $\theta_1^A$  of  $A$  threatens  $S$  while the type  $\theta_2^A$  of  $A$  does not. Following  $A$ 's threat,  $S$  updates her beliefs that  $A$  is of type  $\theta_1^A$ .  $S$ 's payoff if she reports  $\theta_i^S$  is  $V(\bar{s})$  if  $S$  does not pay and  $V(\bar{s} - \eta)$  if she pays.  $S$ 's payoff if she reports  $\ell_2^A$  depends on  $A$ 's report. Notice, however, that  $A$ 's payoff is the same whatever his report. In particular,  $A$ 's payoff is  $\hat{w} - d(x_2 - \theta_1^A) = \bar{w} - \kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A)$  if  $S$  does not pay and  $\hat{w} - d(x_2 - \theta_1^A) + \eta = \bar{w} - \kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A) + \eta$  if  $S$  pays. In either case,  $A$  is indifferent among his messages and hence reports the truth  $\theta_1^A$ . Given this report  $S$ 's payoff is then  $V(\bar{s} - \eta)$

if she does not pay and  $V(\bar{s} - \gamma - \eta)$  if she pays. This implies that  $S$ 's optimal strategy is not to pay  $\eta$  and to report  $\theta_i^S$  while  $A$ 's optimal strategy is to report  $\theta_1^A$ . In other words,  $A$ 's threat is not credible.

Consider next the case in which the type  $\theta_1^A$  of  $A$  does not threaten  $S$  while the type  $\theta_2^A$  of  $A$  does. Following  $A$ 's threat,  $S$  updates her beliefs that  $A$  is of type  $\theta_2^A$ .  $S$ 's payoff if she reports  $\theta_i^S$  is  $V(\bar{s})$  if  $S$  does not pay and  $V(\bar{s} - \eta)$  if she pays. Once again  $S$ 's payoff if she reports  $\ell_2^A$  depends on  $A$ 's report. Notice, however, that as above  $A$ 's payoff is the same whatever his report. In particular,  $A$ 's payoff is  $\hat{w} - d(x_2 - \theta_2^A) = \bar{w} - \kappa$  if  $S$  does not pay and  $\hat{w} - d(x_2 - \theta_2^A) + \eta = \bar{w} - \kappa + \eta$  if  $S$  pays. In either case,  $A$  is indifferent among his messages and hence reports the truth  $\theta_2^A$ . Given this report  $S$ 's payoff is then  $V(\bar{s} + \kappa)$  if she does not pay and  $V(\bar{s} + \kappa - \eta)$  if she pays. This implies that  $S$ 's optimal strategy is not to pay  $\eta$  and to report  $\ell_2^A$  while  $A$ 's optimal strategy is to report  $\theta_2^A$ . Once again,  $A$ 's threat is not credible.

Finally, consider the case in which both types of  $A$  threaten  $S$ . Following  $A$ 's threat,  $S$  does not update her beliefs. Now  $S$ 's payoff if she reports  $\theta_i^S$  is  $V(\bar{s})$  if  $S$  does not pay and  $V(\bar{s} - \eta)$  if she pays. Once again  $S$ 's payoff if she reports  $\ell_2^A$  depends on  $A$ 's report. Notice, however, that as above  $A$ 's payoff is the same whatever his report. In particular, type  $\theta_j^A$ ,  $j \in \{1, 2\}$ , of  $A$ 's payoff is  $\hat{w} - d(x_2 - \theta_j^A) = \bar{w} - \kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_j^A)$  if  $S$  does not pay and  $\hat{w} - d(x_2 - \theta_j^A) + \eta = \bar{w} - \kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_j^A) + \eta$  if  $S$  pays. In either case,  $A$  is indifferent among his messages and hence reports the truth  $\theta_j^A$ . Given this report by (16) and (17)  $S$ 's payoff is smaller than  $V(\bar{s})$  if she does not pay and smaller than  $V(\bar{s} - \eta)$  if she pays. This implies that  $S$ 's optimal strategy is not to pay  $\eta$  and to report  $\theta_i^S$  while  $A$ 's optimal strategy is to report  $\theta_j^A$ . Once again,  $A$ 's threat is not credible. ■

**Lemma A.3:** *The contract CBP is such that, if the supervisor observes the signal  $\theta_2^S$ , there exists no equilibrium collusive agreement such that the supervisor, after observing the signal  $\theta_2^S$ , reports the message  $\theta^S(\theta_2^A) = \hat{\theta}_1^S$  and the  $\theta_2^A$  agent makes a transfer  $\beta(\theta_2^A) \in (0, b)$ , as from equation (12).*

**Proof:** Assume the supervisor observes the signal  $\theta_2^S$ . We proceed in four steps.

**Step 1:** *The agent always reports the truth to the principal whatever his productivity and the outcome of the collusion game.*

We start from the high productivity agent. Assume that the  $\theta_2^A$  agent participates in collusion and the collusion contract is not breached by the supervisor this agent's payoff is then either  $w_{21} - \beta(\theta_2^A) - d(x_2 - \theta_2^A)$ , if he reports the truth, or  $w_{11} - \beta(\theta_2^A) - d(x_{11} - \theta_2^A)$ , if he does not. Equation (10) implies that the agent is indifferent between these two payoffs, hence he reports the truth. Assume next that the  $\theta_2^A$  agent participates in collusion and the collusion contract is breached by the supervisor who reports the message  $\ell_2^A$ . This agent's payoff is then  $\bar{w} - \beta(\theta_2^A) - (1 - \alpha)\kappa$  whether he reports  $\hat{\theta}_2^A$ ,  $\hat{\theta}_2^A$  or  $\mathcal{B}$ . Hence, the agent, being indifferent, reports the truth.

Assume now that the  $\theta_2^A$  agent does not participate in collusion. If the supervisor reports the observed signal  $\theta_2^S$ , the binding incentive compatibility constraint for the high productivity agent, equation (11), implies that the agent reports the truth. If instead the supervisor reports the additional signal  $\ell_2^A$  the agent's payoff

is  $\bar{w} - \kappa$  whether he reports  $\hat{\theta}_2^A$ ,  $\hat{\theta}_2^A$  or  $\mathcal{B}$ . Once again, the high productivity agent being indifferent reports the truth.

Consider, now, the low productivity agent. Assume that the  $\theta_1^A$  agent participates in collusion and the supervisor does not breach the collusive agreement and reports the signal  $\hat{\theta}_1^S$ , the agent's payoff is  $\bar{w} - \beta(\theta_1^A)$  if he reports  $\hat{\theta}_1^A$  and  $w_{21} - \beta(\theta_1^A) - d(x_2 - \theta_1^A) < \bar{w} - \beta(\theta_1^A)$  if he reports  $\hat{\theta}_2^A$ . Hence the agent will report the truth. Conversely, assume that the  $\theta_1^A$  agent does not participate in collusion and the supervisor reports the observed signal  $\hat{\theta}_2^S$ . The incentive compatibility constraint for the low productivity agent — implied by  $\theta_2^A > \theta_1^A$  and equation (11) — holds with strict inequality, hence the agent reports the truth. Finally, assume the supervisor reports the additional signal  $\ell_2^A$ , the agent's payoff is the same whether he reports  $\hat{\theta}_2^A$ ,  $\hat{\theta}_2^A$  or  $\mathcal{B}$ . It is either  $\hat{w} - \beta(\theta_1^A) + \alpha\kappa - d(x_2 - \theta_1^A) = \bar{w} - \beta(\theta_1^A) - (1 - \alpha)\kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A)$ , if the supervisor participated in collusion, breaches the collusion contract and reports the message  $\ell_2^A$  or is  $\hat{w} - d(x_2 - \theta_1^A) = \bar{w} - \kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A)$  if she reports the message  $\ell_2^A$  without participating in collusion. Either case, the agent, being indifferent, reports the truth.

**Step 2:** *Derivation of the supervisor's best response when the supervisor observes  $\theta_2^S$  and does not blackmail the agent.*

Once again, denote  $\nu$  the supervisor's belief that the agent is of type  $\theta_1^A$  at the collusion stage. Assume, first, that both the agent and the supervisor accept to participate in collusion. The supervisor's payoff is then  $V(\bar{s} + \beta(\theta_2^A))$  if she complies with the collusion contract and reports  $\theta^S(\theta_2^A) = \hat{\theta}_1^S$ . The supervisor expected payoff is instead  $\nu V(\bar{s} + \beta(\theta_2^A) - \gamma - \kappa) + (1 - \nu)V(\bar{s} + \beta(\theta_2^A))$  if she breaches the collusion contract and reports the additional signal  $\ell_2^A$ . Equation (14) implies that if  $\nu > 0$  the former option yields a higher payoff to the supervisor, hence she will comply with the collusion contract. If, instead,  $\nu = 0$  the supervisor is indifferent between the two options, hence she acts in the way most preferred by the principal: she breaches the collusion contract and reports the signal  $\ell_2^A$  to the principal.

Consider now the supervisor decision whether to participate in the collusion game. As seen above her payoff, whether she breaches the collusion contract or not, is  $V(\bar{s} + \beta(\theta_2^A))$  while her payoff is  $V(\bar{s})$  if she refuses to participate in the collusion game and reports the observed signal  $\hat{\theta}_2^S$ . Clearly, if  $\beta(\theta_2^A) > 0$  the supervisor is better off accepting to participate in collusion. Only if  $\beta(\theta_2^A) = 0$  the supervisor is indifferent and refuses to participate in the collusion game.

**Step 3:** *If collusion occurs the value of the supervisor's belief  $\nu = 0$  is the only one consistent with the low productivity agent's behavior.*

Assume  $\nu > 0$  and consider the behavior of the low productivity agent. Given the supervisor's best response (Step 2) the agent's payoff is either  $\bar{w} - \beta(\theta_1^A)$ , if he participates in the collusion game, or  $\bar{w}$ , if he does not. Clearly the low productivity agent always refuses to participate in the collusive for  $\beta(\theta_1^A) \geq 0$ . This contradicts the hypothesis  $\nu > 0$ .

**Step 4:** *The agent always refuses to participate in the collusion game whatever his productivity.*

We start from the low productivity agent. Given Step 2 and 3, the agent's payoff is  $\hat{w} + \alpha\kappa - d(x_2 - \theta_1^A) = \bar{w} - (1 - \alpha)\kappa + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A)$  if he participates in the collusion game and produces output  $x_2$ . Such payoff is strictly lower than the agent's reservation wage  $\bar{w}$  since  $\theta_1^A < \theta_2^A$ . Conversely, if the agent refuses to participate in the collusion game his payoff is  $\bar{w}$ , by equation (9). Hence, the low productivity agent refuses to participate in the collusion game.

Finally, consider the high productivity agent. Steps 1, 2 and 3 imply that if he accepts the collusive offer his payoff is  $\hat{w} - \beta(\theta_2^A) + \alpha\kappa - d(x_2 - \theta_2^A) = \bar{w} - \beta(\theta_2^A) - (1 - \alpha)\kappa$ . Conversely, if he rejects the collusive offer his payoff is  $w_{22} - d(x_{22} - \theta_2^A)$  which, by equation (8), is strictly greater than  $\bar{w} - \beta(\theta_2^A) - (1 - \alpha)\kappa$ . Hence, the high productivity agent refuses to participate in the collusion game. ■

**Lemma A.4:** *The contract CBP is such that there exists no equilibrium collusive agreement where:*

(i) *The supervisor reports the message  $\hat{\theta}^S(\theta_1^A) = \hat{\theta}^S(\theta_2^A) = \ell_2^A$ , the agent reports  $\hat{\theta}^A(\theta_1^A) = \hat{\theta}^A(\theta_2^A) = \hat{\theta}_2^A$  and the supervisor pays the bribe  $\xi \in (0, \kappa)$  to the agent.*

(ii) *The supervisor reports the message  $\hat{\theta}^S(\theta_2^A) = \ell_2^A$ , the  $\theta_2^A$  agent reports  $\hat{\theta}^A(\theta_2^A) = \theta_2^A$  and the supervisor pays the bribe  $\xi \in (0, \kappa)$  to this type of agent. The  $\theta_1^A$  agent does not participate in collusion.*

**Proof:** Consider first the collusive agreement described in (i) above:  $\hat{\theta}^S(\theta_1^A) = \hat{\theta}^S(\theta_2^A) = \ell_2^A$ ,  $\hat{\theta}^A(\theta_1^A) = \hat{\theta}^A(\theta_2^A) = \hat{\theta}_2^A$  and the supervisor pays the bribe  $\xi \in (0, \kappa)$  to the agent. The  $\theta_1^A$  agent's highest payoff ( $\xi = \kappa$ ) if he participates in collusion is  $\hat{w} - d(x_2 - \theta_1^A) + \kappa = \bar{w} + d(x_2 - \theta_2^A) - d(x_2 - \theta_1^A) < \bar{w}$ . Hence, the  $\theta_1^A$  agent does not participate in such a collusion agreement since he can guarantee himself a payoff of  $\bar{w}$  by doing so.

Consider now the collusive agreement described in (ii) above:  $\hat{\theta}^S(\theta_2^A) = \ell_2^A$ ,  $\hat{\theta}^A(\theta_2^A) = \theta_2^A$ , the supervisor pays the bribe  $\xi \in (0, \kappa)$  to the  $\theta_2^A$  agent and the  $\theta_1^A$  agent does not participate in collusion. The  $\theta_2^A$  agent's highest payoff ( $\xi = \kappa$ ) if he participates in collusion is  $\hat{w} - d(x_2 - \theta_1^A) + \kappa = \bar{w}$ . Hence, the  $\theta_2^A$  agent does not participate in such a collusion agreement since he can guarantee himself the same payoff of  $\bar{w}$  by doing so. ■

**Proof of Proposition 3:** Notice that given contract *CBP* there only exist gains-from-trade from collusion in two separate instances. When  $S$  observes  $\theta_2^S$  the type  $\theta_2^A$  of  $A$  is willing to pay up to  $b$  as in (12) above for  $S$  to report  $\hat{\theta}_1^S$  rather than  $\hat{\theta}_2^S$ . When  $S$  reports message  $\ell_2^A$  she is willing to pay up to the amount  $\kappa$  for the agent to report  $\hat{\theta}_2^A$  rather than  $\hat{\theta}_1^A$  or  $\mathcal{B}$ .<sup>32</sup>

Lemma A.3 and Lemma A.4 show that neither type of collusion may occur in any equilibrium of our model under contract *CBP*. In the absence of collusion, Lemma A.1 and A.2 show that under contract *CBP* no blackmail on the part of the agent or of the supervisor will occur in equilibrium. It then follows that, under contract *CBP*, all the PBE of the continuation game between the supervisor and the agent coincides with the PBE of the corresponding continuation game under the *honest* contract. ■

<sup>32</sup>In the latter case  $S$  is willing to pay more:  $\kappa + \varepsilon$ .
